# The Global Stocktake

## Timeline for the Paris Agreement Ambition Mechanism

The Global Stocktake every 5 years (starting in 2023) will assess progress and adjust commitments towards the Paris Accord.

### Ambition Mechanism

The "ambition mechanism" commits countries to take stock of progress every 5 years. As part of this process, countries will ramp up climate action to reach net zero.

2060

### Achieving Stability

In the Paris Agreement, 196 governments committed to hold the temperature rise well below 2°C, pursue efforts to limit the rise to 1.5°C, and to make sure humans are not emitting more than the planet can absorb. That means we need to reach net zero GHG emissions in the second half of the century.

For 1.5°C, GHG emissions will need to reach net zero by 2060-2080; for 2°C, net zero GHG must be reached by 2080-2100.\*

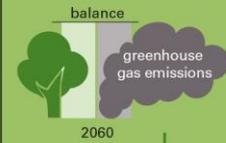

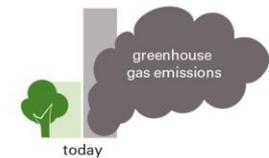

*How will emission commitments be related to concentration requirements?*

action by developing 2050 plans that build citizen and business support

# The gap between fluxes and concentrations

In an ideal system, the time-to-detection of total CO<sub>2</sub> flux trends for many parts of the world is within 10-15 years (2-3 stocktakes). But, the relationship between those trends and FF trends is complex

In China, about 20% of total CO<sub>2</sub> trends is within 25% of the underlying FFCO<sub>2</sub> trends

Both anthropogenic and natural processes drive trends at stocktake scales

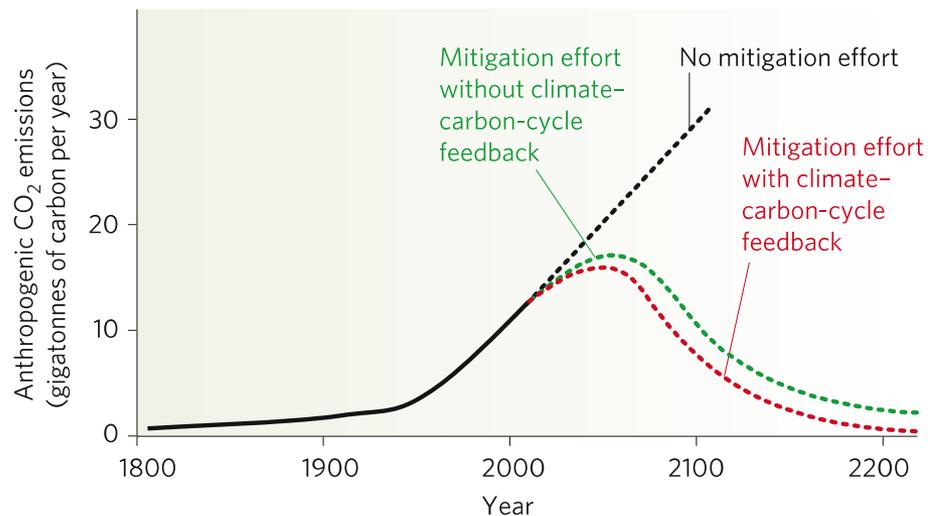

# Confounding variables: Carbon-climate feedbacks

## A steep road to climate stabilization

Pierre Friedlingstein

The only way to stabilize Earth's climate is to stabilize the concentration of greenhouse gases in the atmosphere, but future changes in the carbon cycle might make this more difficult than has been thought.

## Trends in the sources and sinks of carbon dioxide

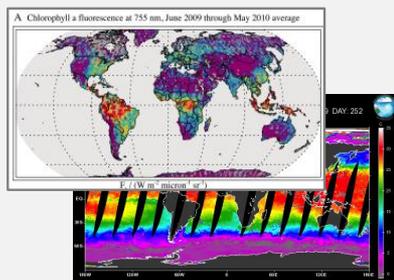

Corinne Le Quéré, Michael R. Raupach, Josep G. Canadell, Gregg Marland *et al.*\*

“major gaps remain...in our ability to link anthropogenic CO<sub>2</sub> emissions to atmospheric CO<sub>2</sub> concentration on a year-to-year basis... and adds uncertainty to our capacity to quantify the effectiveness of climate mitigation policies.”

Both fossil fuel FFCO<sub>2</sub> (forcing) and net CO<sub>2</sub> (forcing and feedbacks) trends are important.  
How are they related globally?

Liu et al, ERL, 2018

The NASA Carbon Monitoring System Flux (CMS-Flux) attributes atmospheric carbon variability to spatially resolved fluxes driven by data-constrained process models across the global carbon cycle.

# Brazilian carbon balance, 2010-2011

- The Modoki El Nino from 2010-2011 led to historic droughts in Brazil
- CMS-Flux results indicate that the change in total flux was driven by biomass burning.
- Brazil was the largest contributor to the global biomass burning anomalies
- Productivity increases were offset by equivalent and respiration.

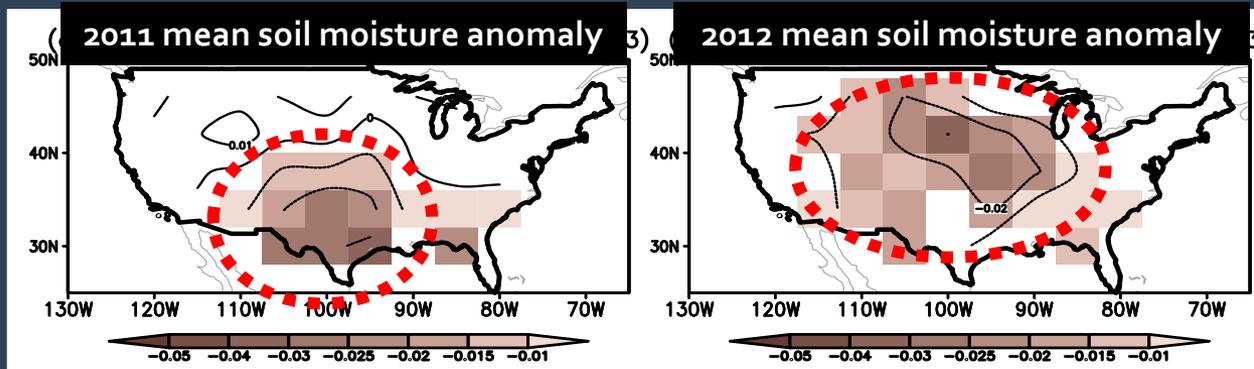

$$F^{\uparrow}(x, y, t) = F_F + F_O + F_{BB} + \underbrace{(R - GPP_{SIF})}_{-F_{NEP}} + F_{chem}$$

Net flux into the atmosphere is positive PgC

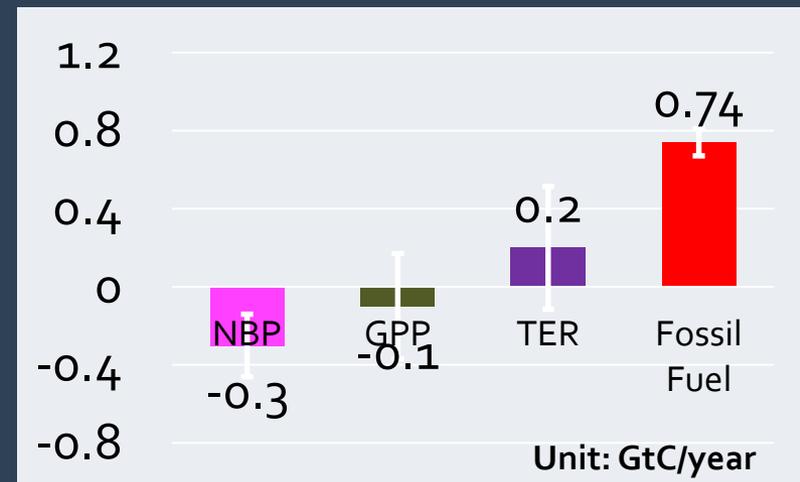

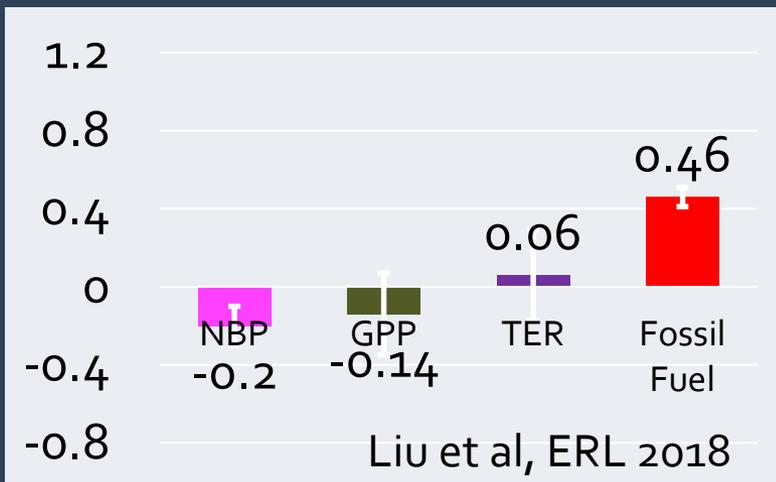

# Impact of drought during 2011 and 2012 on NBP anomalies

The 2011 dry spell in Texas was the worst one-year period of drought since 1895, and the area span of 2012 summer drought was comparable to the dust bowl era.

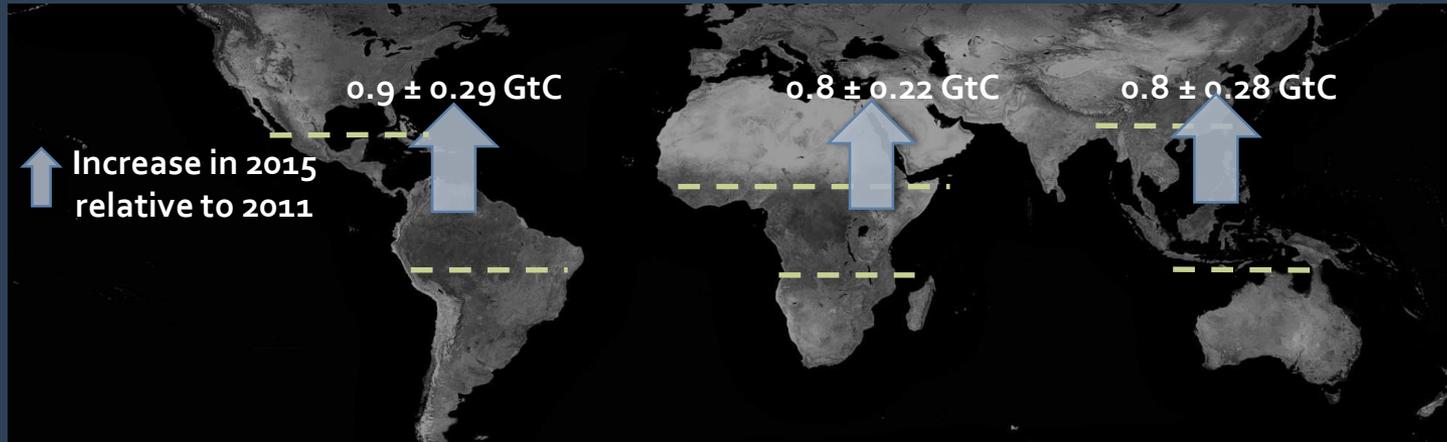

The NBP reduction due to the drought was **more than 40%** of the regional fossil fuel emissions

2012 NBE seasonal anomalies consistent with flux towers results in Wolf et al, 2016)

# A Tale of 3 continents: the 2015 El Nino

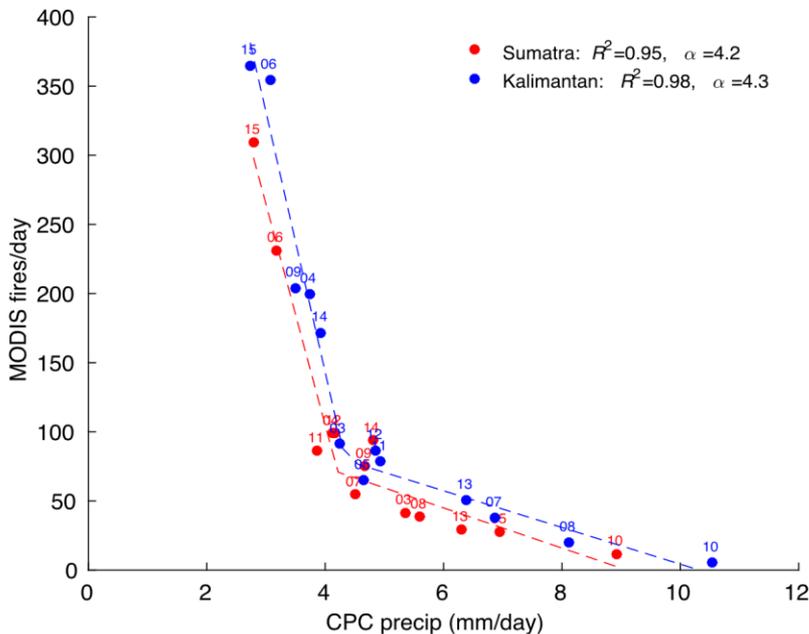

Liu et al, Science, 2017

The Tropics released  $2.5 \pm 0.34$  Gt more carbon into the atmosphere in 2015 than in 2011.

# Tipping points: the hydrological context

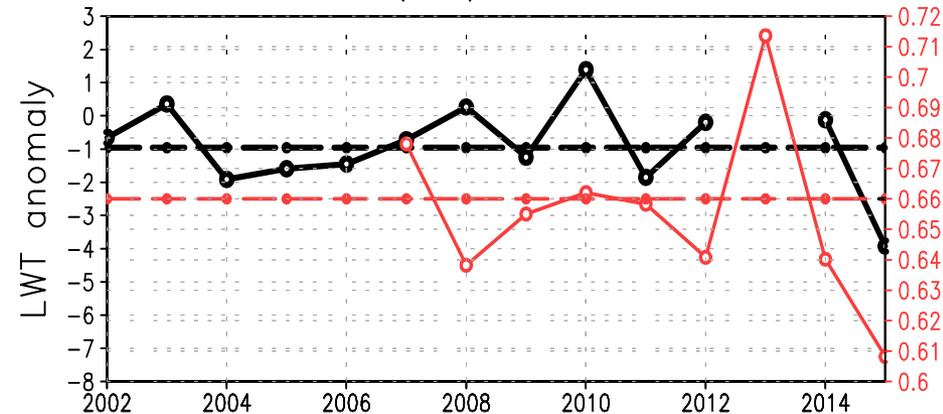

Centered on Kalimantan, GRACE gravity data shows a liquid water equivalent thickness (LWT) anomaly of -4 cm, 4x larger than then decadal mean anomaly.

Field et al, 2016 PNAS reported a non-linear relationship between firecounts and precipitation below 4 mm/day

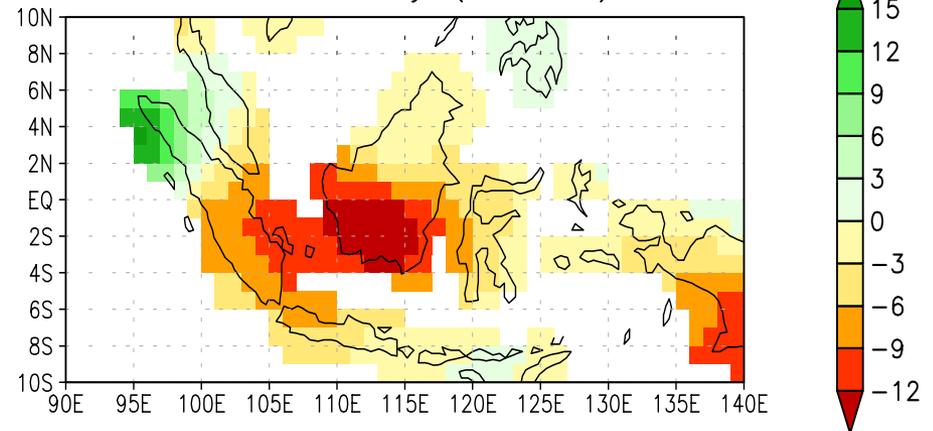

Fields et al, 2016 (PNAS)

# Atmospheric signature of Indonesian carbon in 2015

Dr. Richard Weidner  
Date: 2015.09:01 00

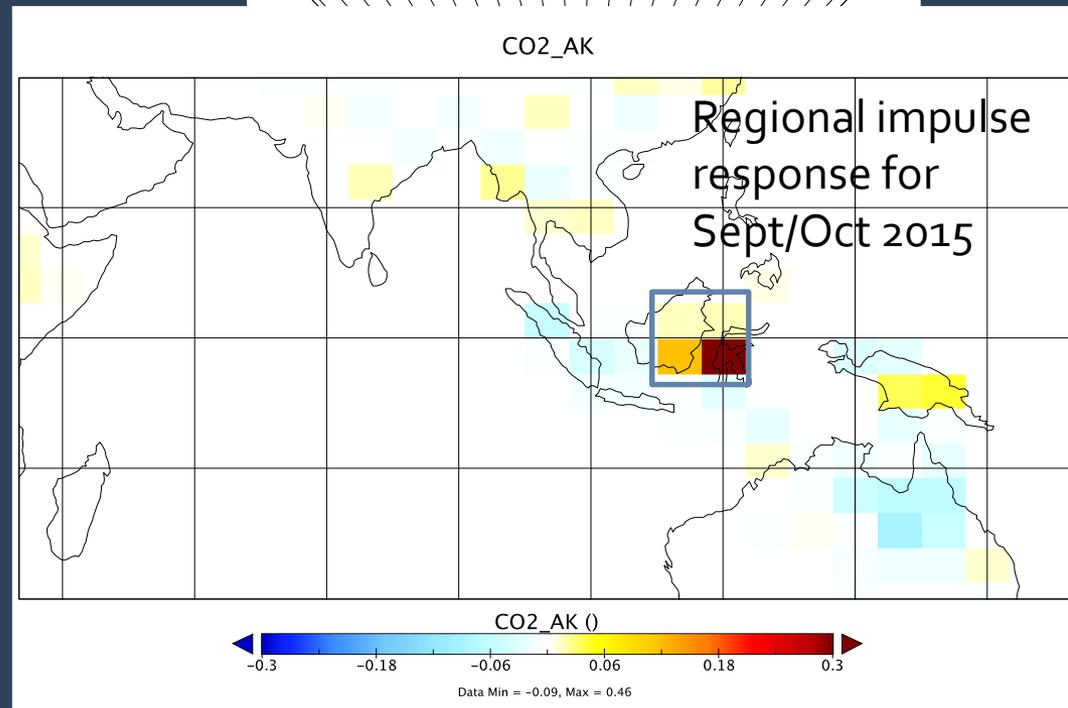

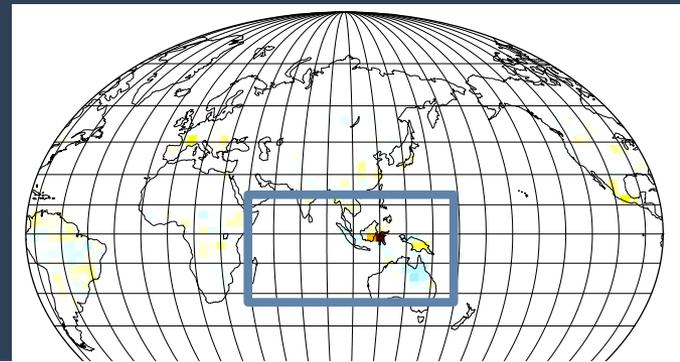

# Resolving Indonesian Flux

The sensitivity of the CMS-Flux Indonesian flux estimate to the true flux is defined by the impulse response (IR):

$$\frac{\partial \hat{\mathbf{x}}}{\partial [\mathbf{x}]_{i \in L}}$$

The IR response shows the fractional change in the OCO-2-constrained global flux if the *true* flux increased by 100%.

The IR can be approximated following techniques in Bousseret and Henze, 2018, which synthesize advances in probabilistic matrix decomposition and estimation techniques

The high values over Indonesia and Borneo (and weaker responses elsewhere) show that the the peak biomass burning in Sept/Oct 2015 is well resolved by CMS-Flux.

# Validation of carbon fluxes

Direct validation of large-scale fluxes is difficult. Posterior CO<sub>2</sub> can be compared to independent data. How do they relate to fluxes? Following Liu and Bowman, 2016 (GRL)

$$J_{prior}(\mathbf{x}_a) = \|CO2_{prior} - CO2_{site}\|^2$$

$$J_{post}(\hat{\mathbf{x}}) = \|CO2_{post} - CO2_{site}\|^2$$

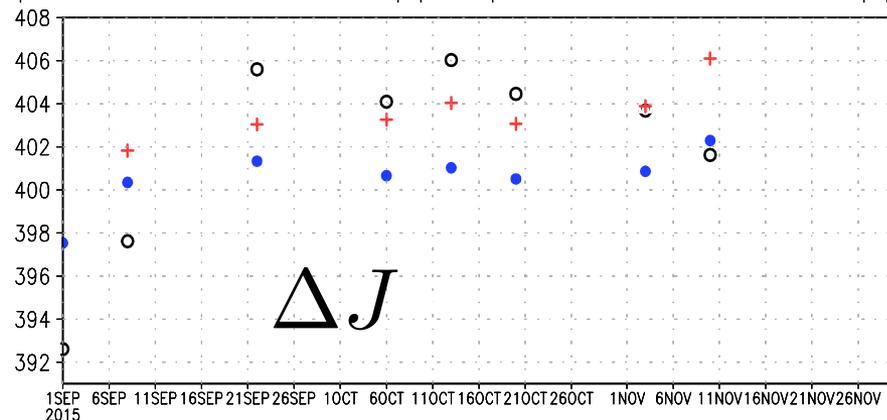

$$\Delta J = J_{post} - J_{prior}$$

$$\nabla_{\mathbf{x}}(\Delta J)$$

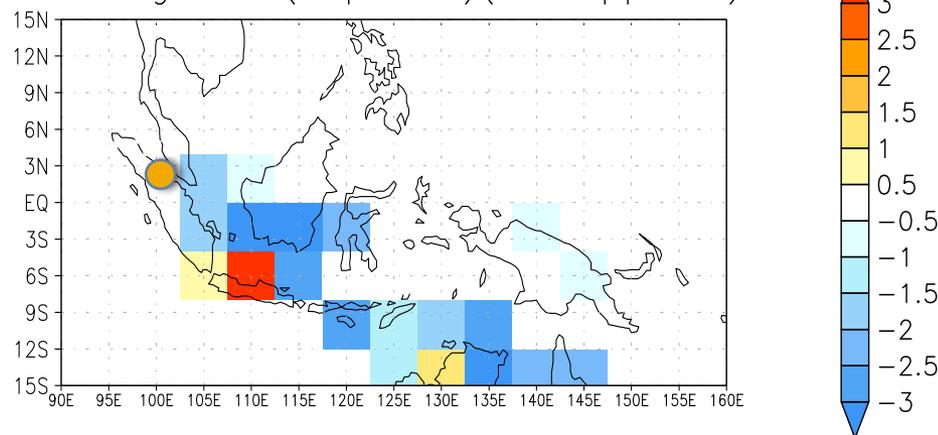

Fluxes in S. Kalimantan improved agreement with the background site by >3ppm<sup>2</sup> or ~5% of total improvement.

Underestimate w.r.t. site suggests fluxes are likely underestimated.

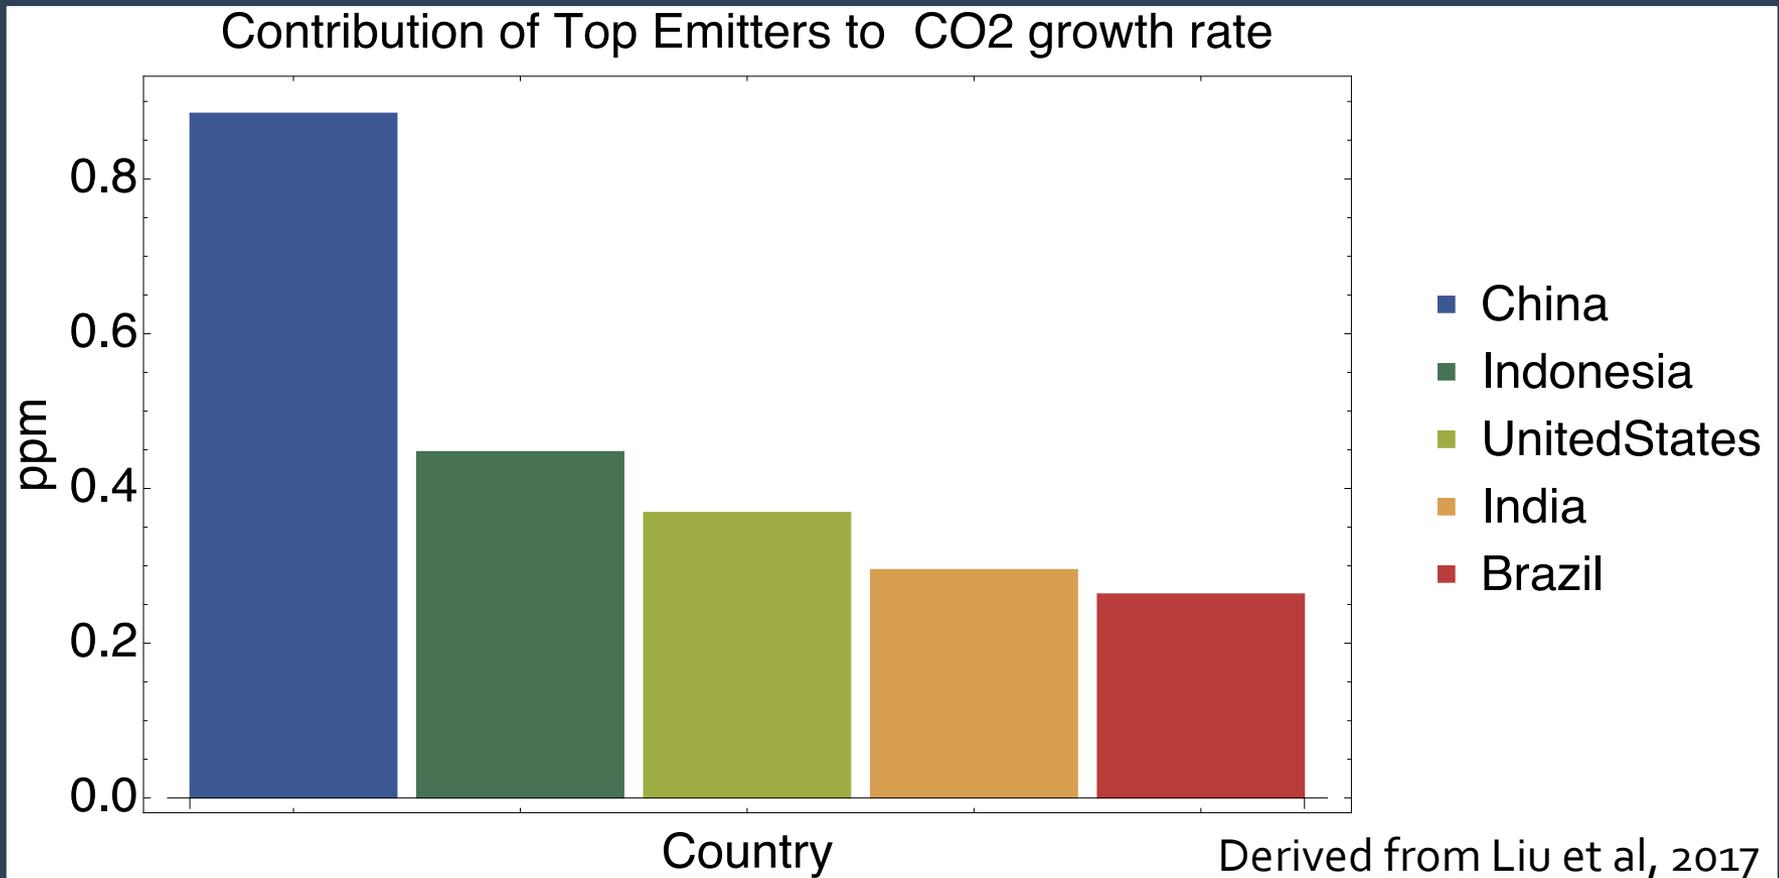

black: obs; blue: prior; red: posterior  
prior RMS=3.71991ppm, post RMS=2.69766ppm

reduction of CO<sub>2</sub> RMS error at bkg site (Sep+Oct)(unit: ppm<sup>2</sup>)

# Contributions to the CO<sub>2</sub> growth rate

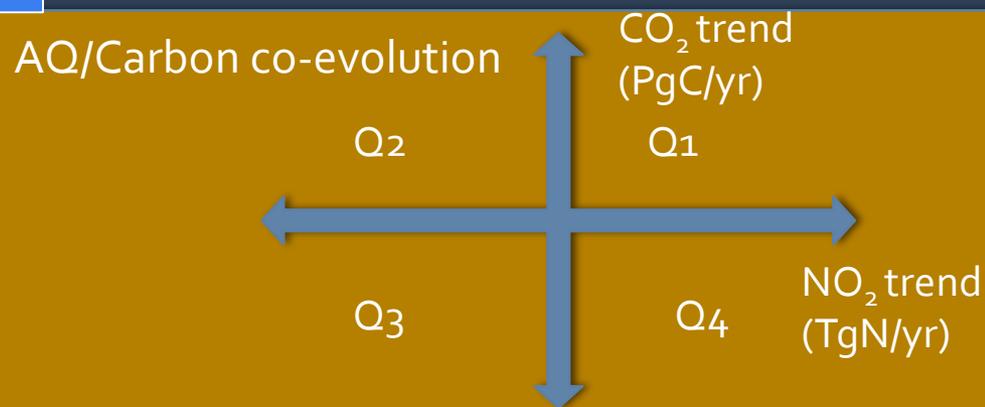

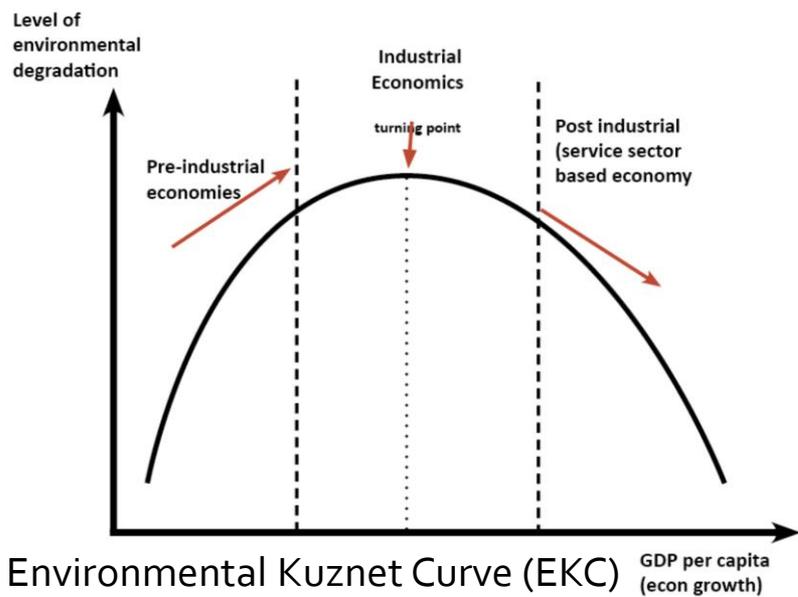

CMS-Flux was used to show that China was the highest and Indonesian region was the 2<sup>nd</sup> highest contributor (0.45 ppm) to total flux of the record CO<sub>2</sub> growth rate in 2015.

Both those were due to different drivers.

# The ties that bind: air quality and carbon

The primary environmental concern in most developing countries is air quality, not carbon.

How will changes in air quality mitigation impact carbon emissions? Do they have similar or conflicting environmental Kuznet curves?

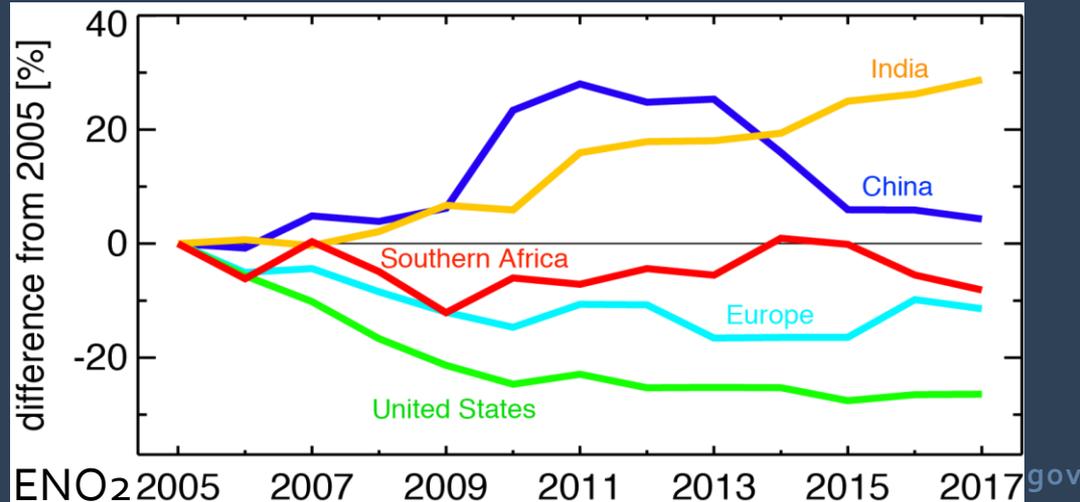

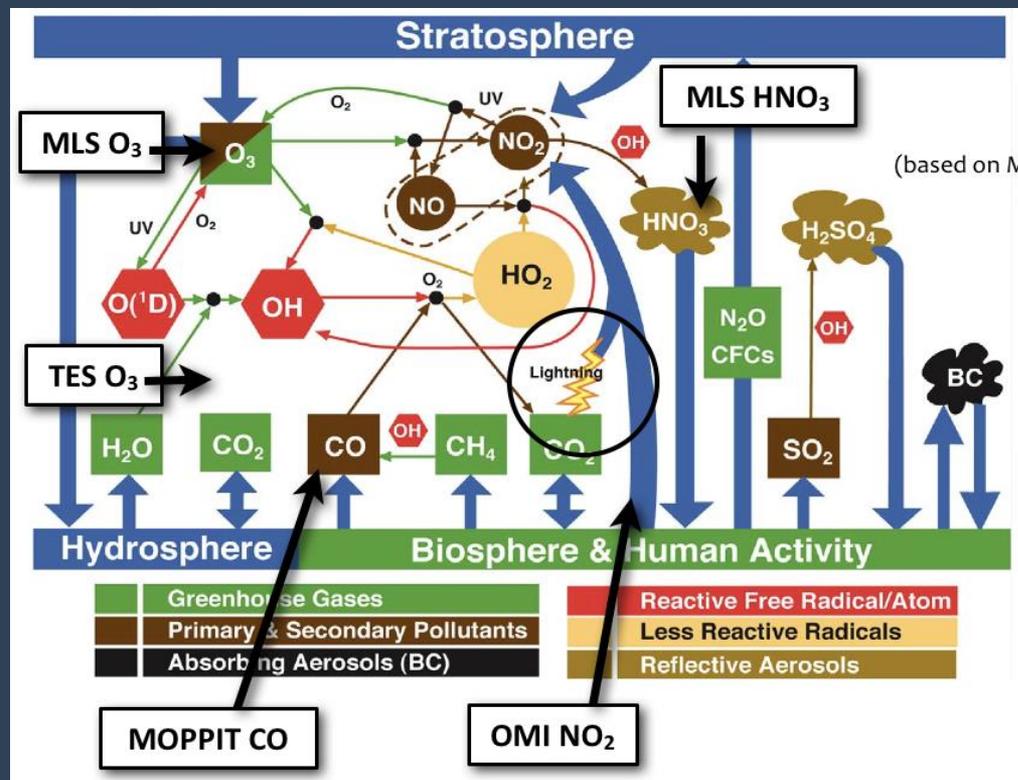

- Q1: Business as usual (BAU)
- Q2: AQ-only (CO<sub>2</sub> lock-in?)
- Q3: AQ/Carbon (renewables)
- Q4: Carbon-only

# JPL/JAMSTEC chemical reanalysis

The tropospheric chemistry reanalysis (TCR-2) assimilated data from multiple satellites (Miyazaki et al, 2012-2019).

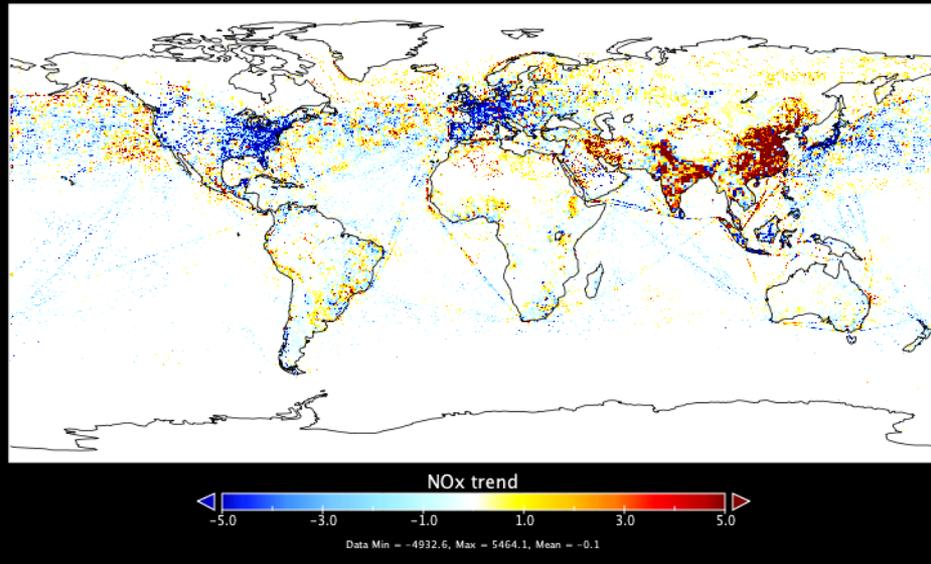

Migration towards AIRS/OMI O<sub>3</sub> (Miyazaki et al, 2019) and TROPOMI data streams in progress.

NO<sub>x</sub> emissions have been computed from 2005-2017 at 1x1 grid resolution.

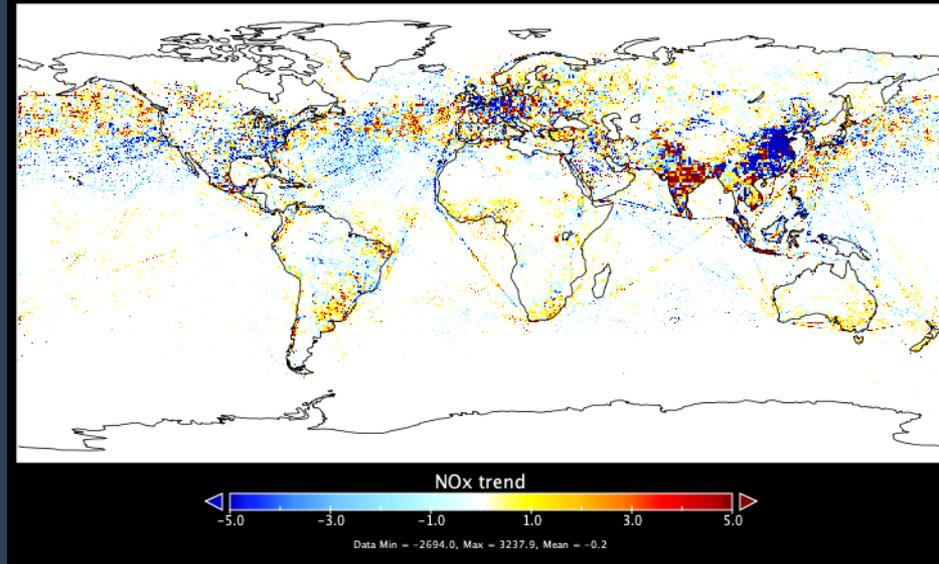

# The Changing Landscape of Emissions

TCR-2 NO<sub>x</sub> trend : 2005-2010

TCR-2 NO<sub>x</sub> trend : 2011-2017

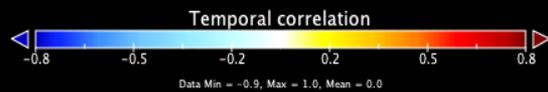

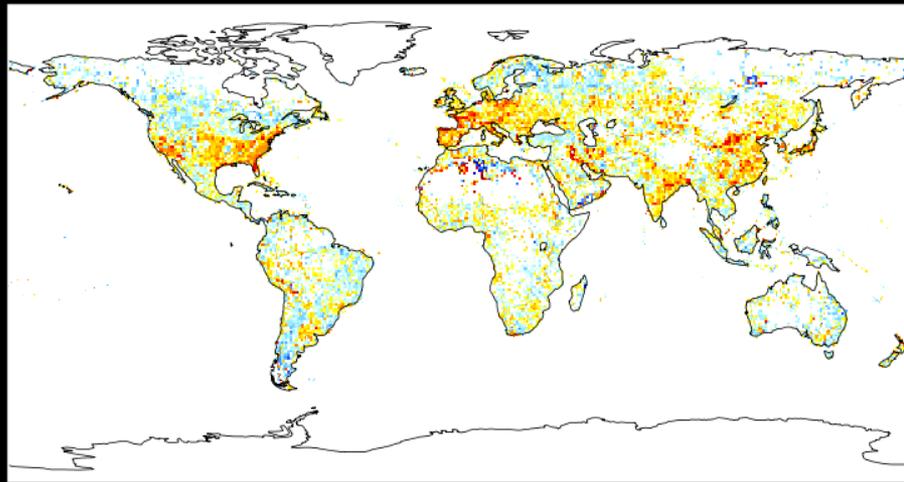

The JPL/JAMSTEC multi-constituent data assimilation analysis (TCR-2) shows rapid changes in Chinese NO<sub>x</sub> emissions—within one stocktake.

These results also show a slow-down in US emissions as reported in Jiang *et al*, PNAS (2018).

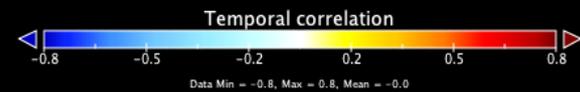

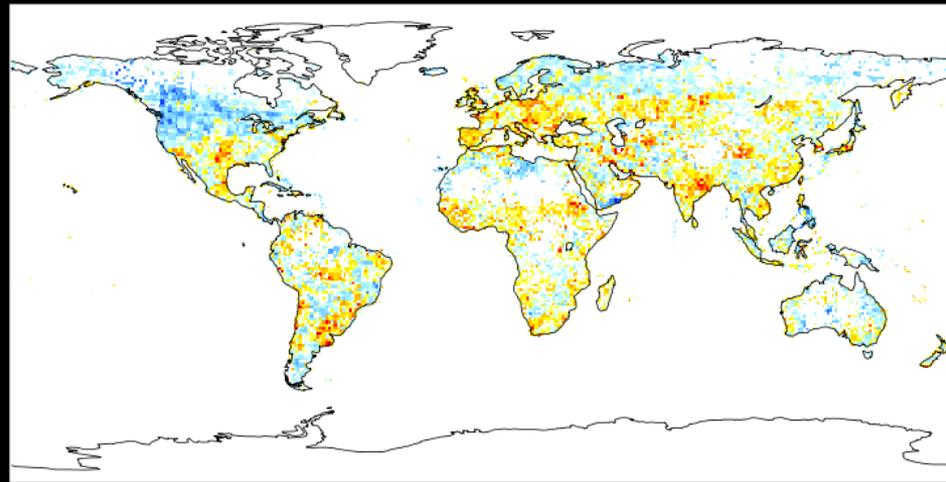

What do these changes imply about the carbon footprint?

# Changing landscape of correlations

ODIAC CO2 vs TCR-2 NOx : 2005-2010

ODIAC CO2 vs TCR-2 NOx : 2011-2017

There is a substantial change in CO<sub>2</sub>:NO<sub>2</sub> correlations between 2005-2010 and 2011-2017 from ODIAC and TCR-2.

Nation	2005-2010 (R)	2011-2017 (R)
US	0.55	0.11
Europe	0.36	0.25
India	0.20	0.36
China	0.36	-0.34

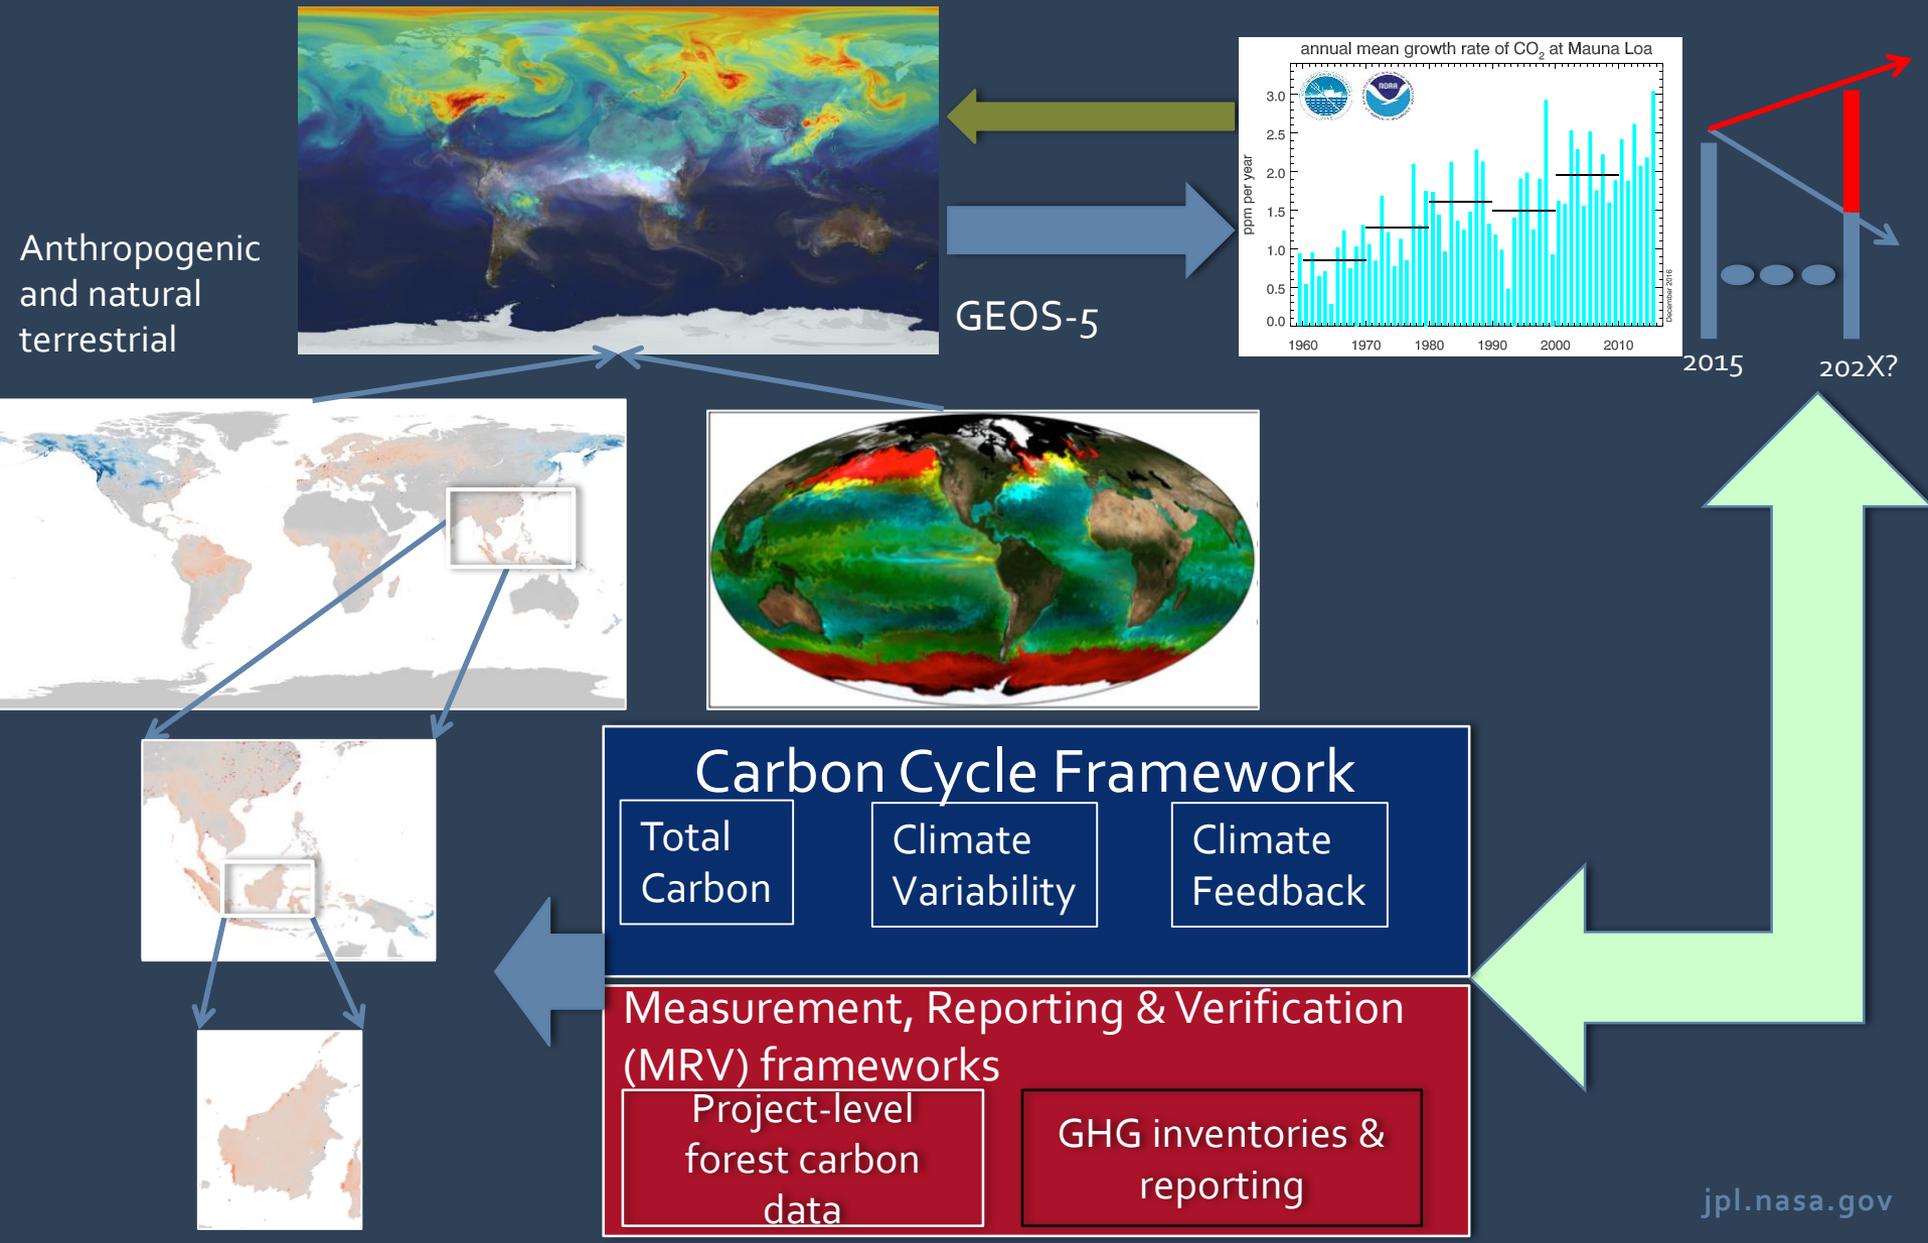

This suggests that either CO<sub>2</sub> predictions have degraded (NA and Europe) or emission factors are dynamic.

A changing GHG/AQ Kuznet process?

# Conclusions

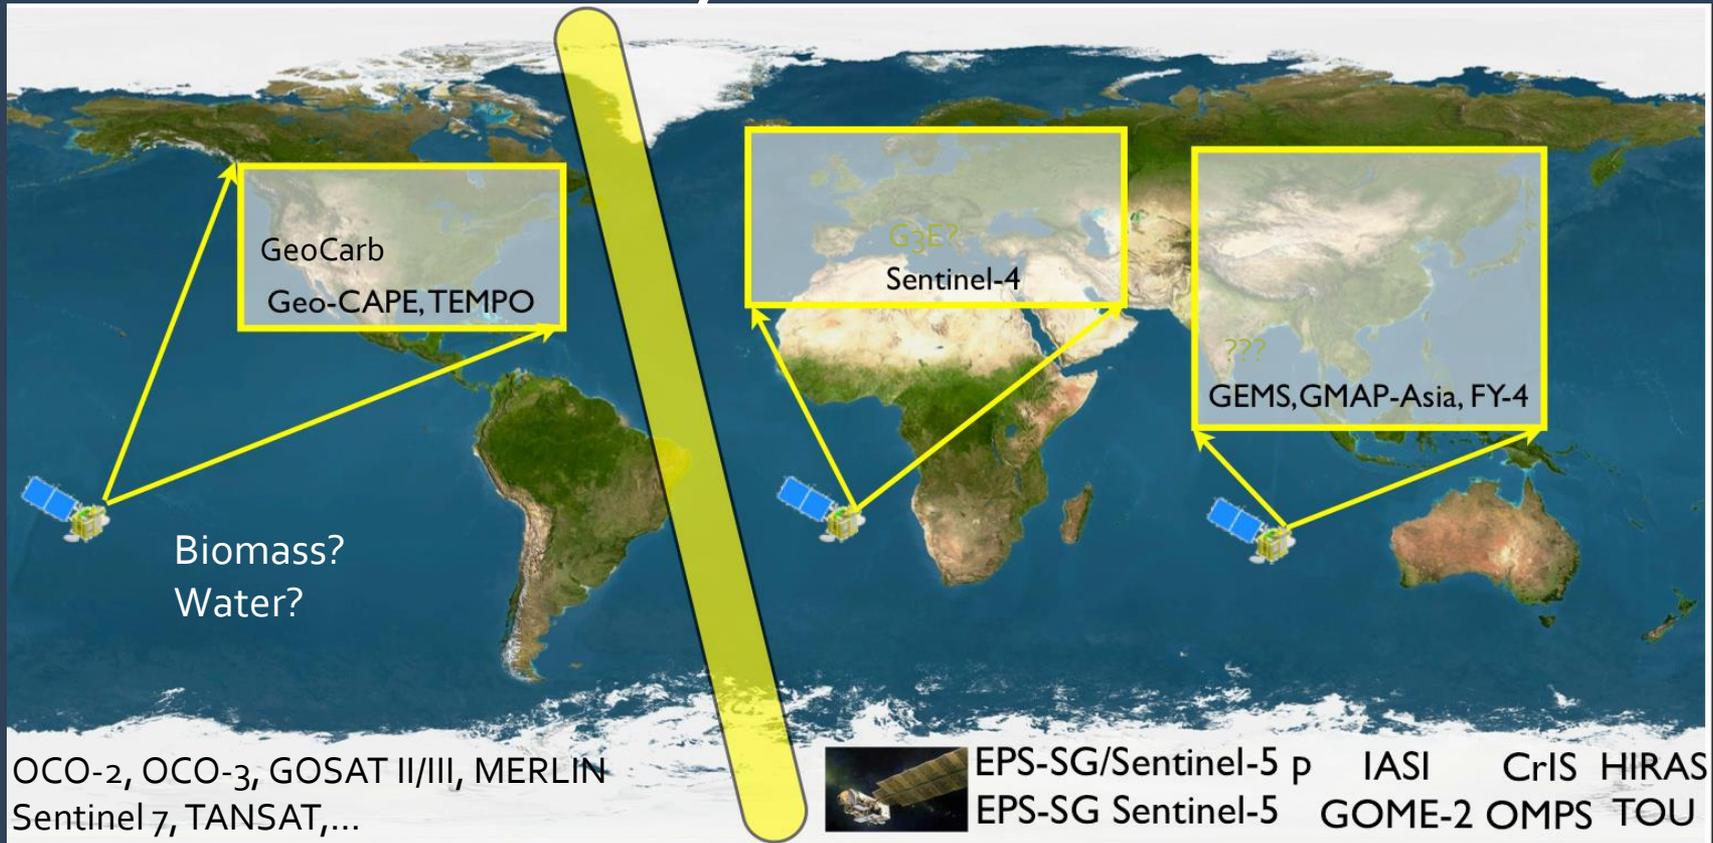

- The bidecadal stocktake requires a link between
  - net CO<sub>2</sub> flux  $\leftarrow \rightarrow$  Concentrations (what the climate sees)
  - FFCO<sub>2</sub>  $\leftarrow \rightarrow$  Emissions (what carbon mitigation sees)
- Only atmospheric-based systems, not the UNFCCC inventories, can make that link.
- Trends at stocktake scales will be a mixture of anthropogenic and carbon processes
  - Attribution of decadal oceanic carbon trends need to be considered (ECCO-Darwin)
  - The predictability of the carbon cycle is important (CARDAMOM)
- CMS-Flux results show the intimate relationship between hydrological and carbon cycles that will impact those trends
- Exploitation of the full carbon and air quality constellation at multiple scales is critical to advance the objectives of the Paris accord and guide observing system requirements.

# Carbon-Climate Framework

# Toward an Air Quality-Carbon-Climate

Bowman et al, Atm.Env. 2013

- LEO:
  - IASI+GOME-2, AIRS+OMI, CrIS+OMPS could provide UV+IR ozone products for more than a decade.
  - Combined UV+IR ozone products from GEO-UVN and GEO-TIR aboard Sentinel 4 (Ingmann *et al*, 2012 Atm. Env.)
  - Sentinel 5p (TROPOMI) will provide column CO and CH<sub>4</sub>.
  - OCO-2+AIRS, GOSAT II (IR+NIR) could provide vertical discrimination.
- GEO
  - TEMPO, Sentinel-4, and GEMS, would provide high spatio-temporal air quality information.
  - GeoCarb and G3E could provide geo-carbon information.

# Regional variations in trends

There is a wide intra-regional range of TTD with the Middle East having the lowest range 5 years (5-10 1<sup>st</sup> and 3<sup>rd</sup> quartile), though Europe and China TTD 3<sup>rd</sup> quartile is within 20 years.

For, FFCO<sub>2</sub> trends greater than 5 gC/m<sup>2</sup>/yr<sup>2</sup>, ~1/3 corresponding net CO<sub>2</sub> trends agree to within 25%.

Similarly in China, ~20% of the net CO<sub>2</sub> trends agree to within 25%.

In the Middle East, over 70% of net CO<sub>2</sub> trends is within 25%
