Wageningen University
12/03/2019
Corrine le Quéré, UEA, UK

This project has received funding from the European Union's Horizon 2020
research and innovation programme under grant agreement No 776186.

WP Objectives

- Deliver a cross section of remote-sensing data products needed in the data assimilation chain to constrain anthropogenic carbon emissions
- Develop novel techniques to constrain anthropogenic and natural carbon emissions from joint surface and space- based carbon cycle data
- Reconcile top-down and bottom-up carbon dioxide source/sink estimates at multiple levels of integration using a community access platform
- Document current shortcomings and needed developments in space-based monitoring of fossil fuel CO₂ emissions

Task 1: Improve the processing chain for data assimilation

- *Objective*
 - Provide a number of key datasets needed in carbon cycle data assimilation systems that estimate natural and anthropogenic CO₂ emissions
- *Progress*
 - Protocols for delivery of satellite data, emission data, observational data were made
 - Protocols for delivery of model output were made (**next slide**)
 - New U. of Bremen OCO-2 XCO₂ satellite data product created under CHE released (**example follows**)
 - Sun-induced fluorescence datasets (NASA-GOME, KNMI-SIFTER) and XCO₂ datasets (NASA OCO-2, GoSAT) made accessible for partners
 - Common bottom-up fossil fuel emission datasets, and observational CO₂ data (ObsPack) created and disseminated
 - One change to Work Plan: New Leicester custom GoSAT and OCO-2 retrieval product (**details follow**)

D1.1 Protocol defining harmonized input and output datasets

Authors: Liesbeth Florentie (Wageningen University)

Abstract

The current document outlines minimum requirements for input and output datasets as emerging from WP1 of the CO₂ Human Emissions (CHE) project. The aim of this protocol consists of harmonizing the different datasets to ensure compatibility and easy accessibility for subsequent integral analyses. Special attention is given to both the set-up and data format of CO₂ surface flux inversions, which will be used to assess the effectivity of proposed methodological innovations.

OCO-2

CAMS

April 2015

August 2015

Data quality via comparison with **TCCON**:

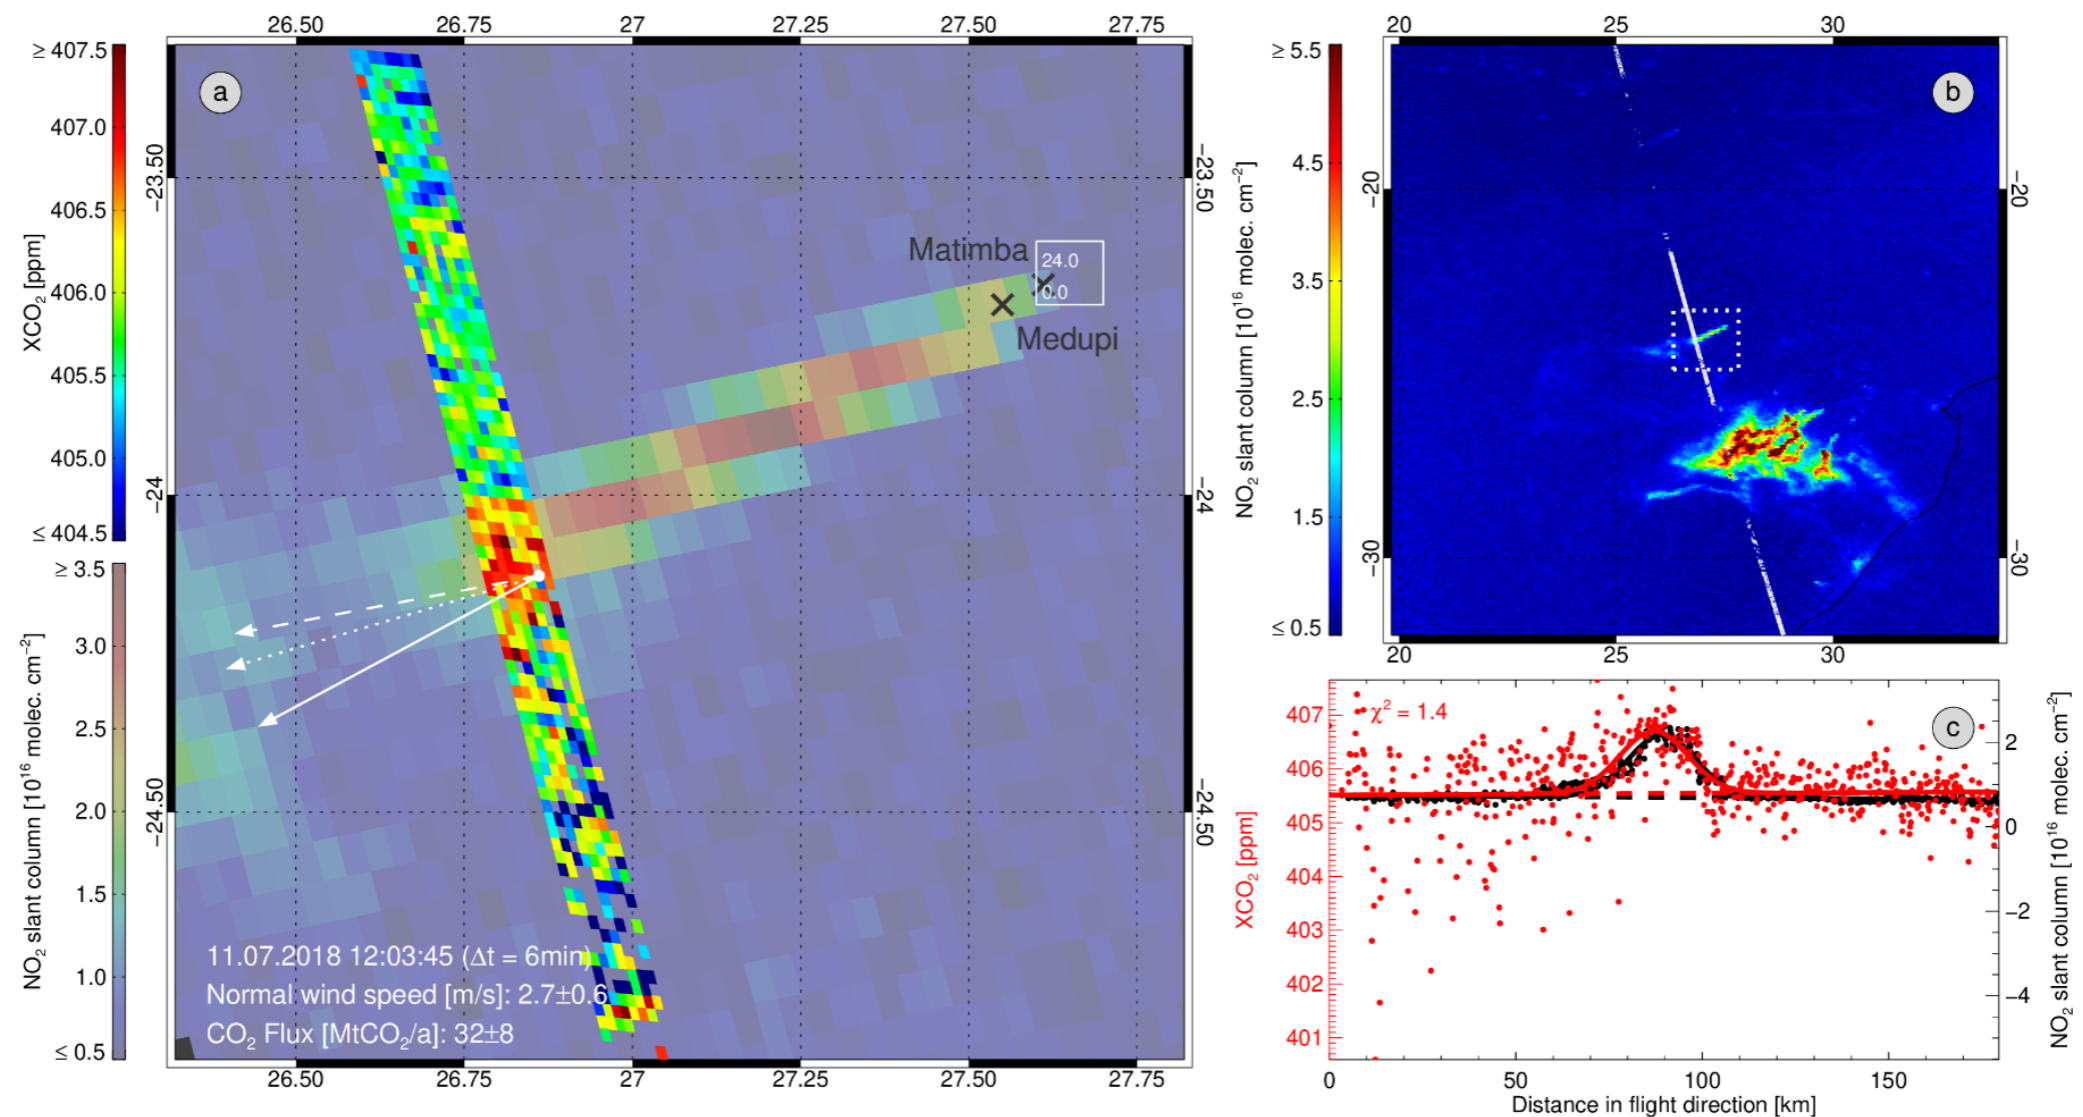

- Systematic (bias): 0.58 ppm; random (scatter): +/- 1.5 ppm (1-sigma)

Use of OCO-2 XCO₂ and S5P XNO₂ for anthropogenic emissions (-> link to task 3 in WP3)

Estimation of CO₂ fluxes from localized anthropogenic emission sources using co-located OCO-2 CO₂ and S5P NO₂ observations (TropOMI)

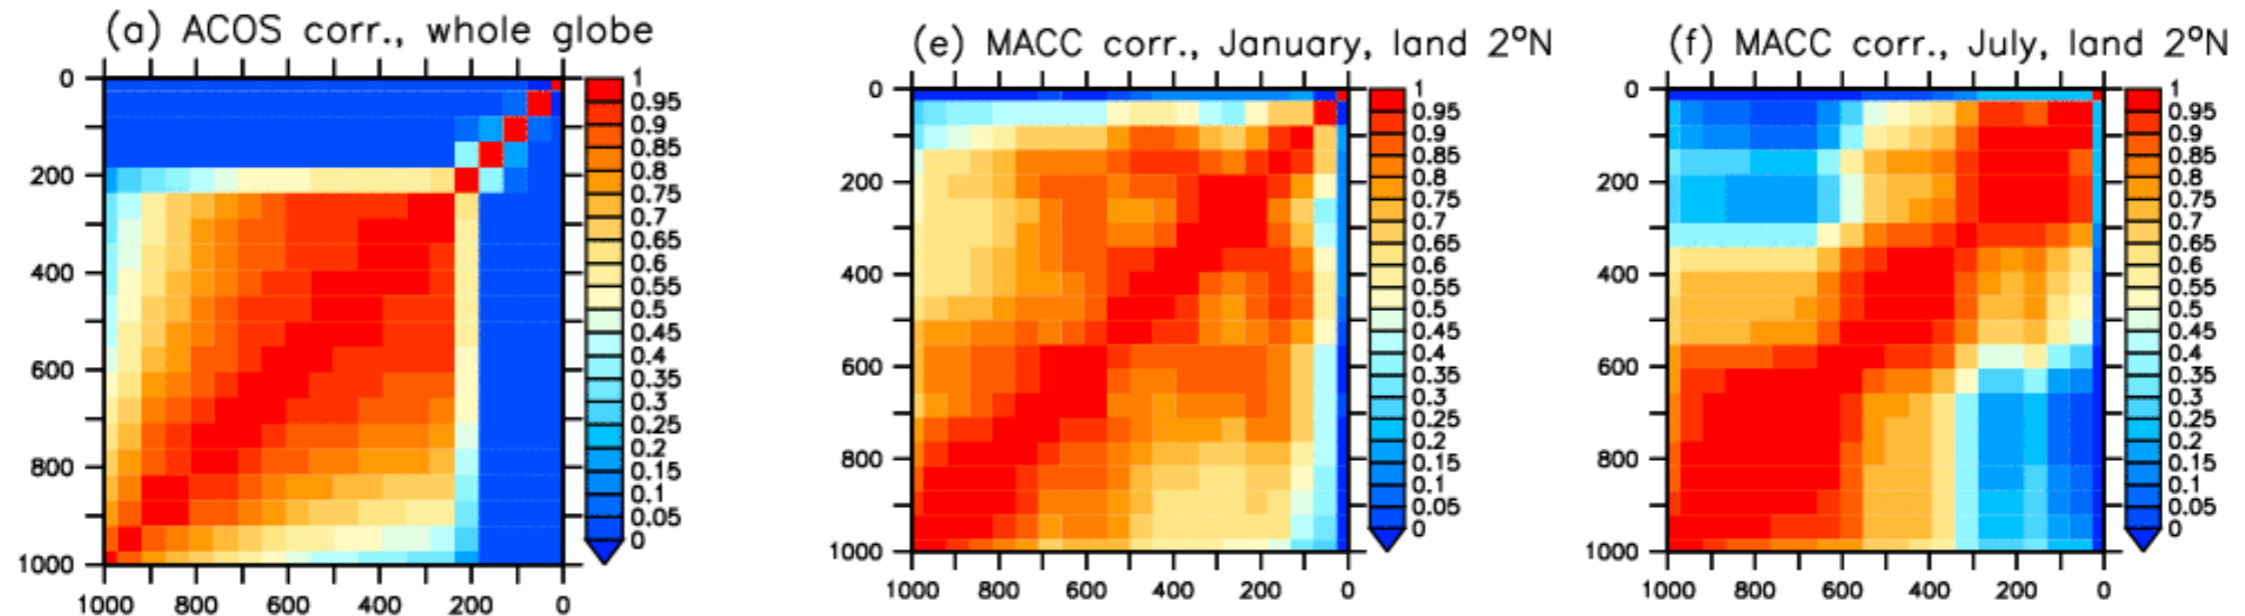

(Reuter et al., ESA ATMOS 2018)

Example: South African power plants Medupi (4.8GW) and Matimba (4.0GW)

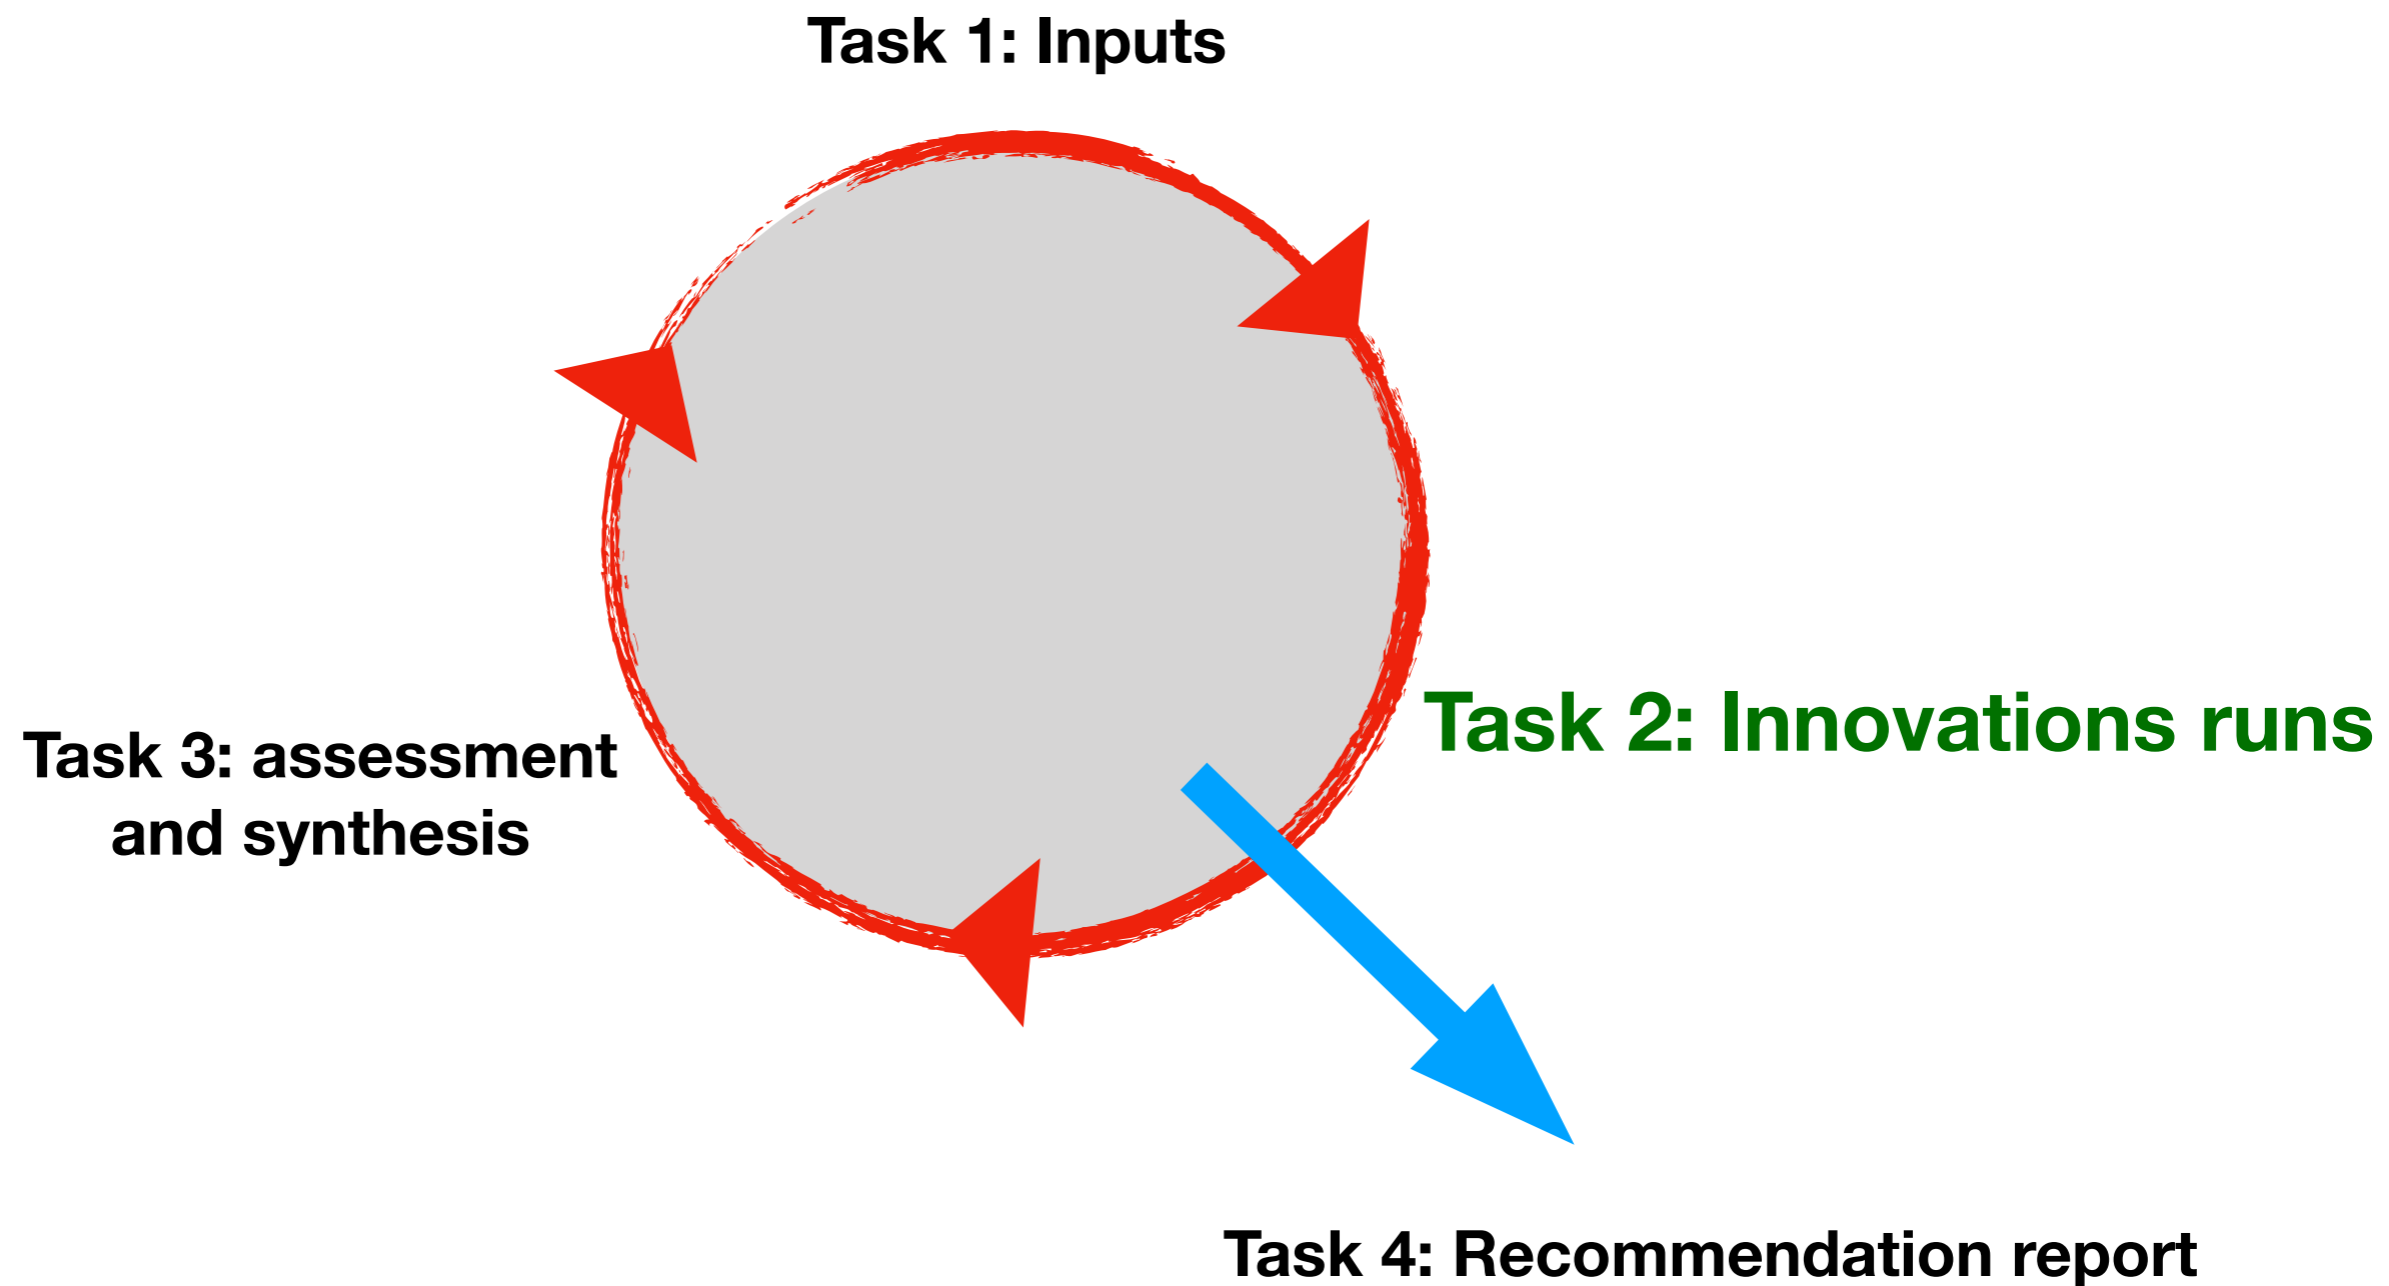

Leicester task: ~~Bias in XCO₂ retrievals~~

Correlated errors in XCO₂ retrievals

- Change in focus as response to concern of modeling groups
- **Goal of this task:** Retrieve XCO₂ while including the vertical error correlations of underlying unknown fluxes to get consistent representation of inverse modeling system assumptions
- Sounding specific covariance used in retrieval, derived from model covariances representing the MACC/LSCE prior flux uncertainties projected in space and time (F. Chevallier, LSCE)
- Prior flux uncertainty will be propagated using linear analysis to re-generate 1 Year dataset for GOSAT XCO₂ based on C3S L2 (mid-2019) and for OCO₂ L2 data based on NASA L2 (end-2019)
- Full non-linear CO₂ retrievals for 1 Year dataset of GOSAT (early 2020) will also be carried out
- The modified XCO₂ datasets will then be used in MACC inverse scheme under Task 2, addressing “grand challenge” of including consistent errors in processing chain.

Task 2: Develop novel data fusion techniques for joint surface and space-based carbon cycle data

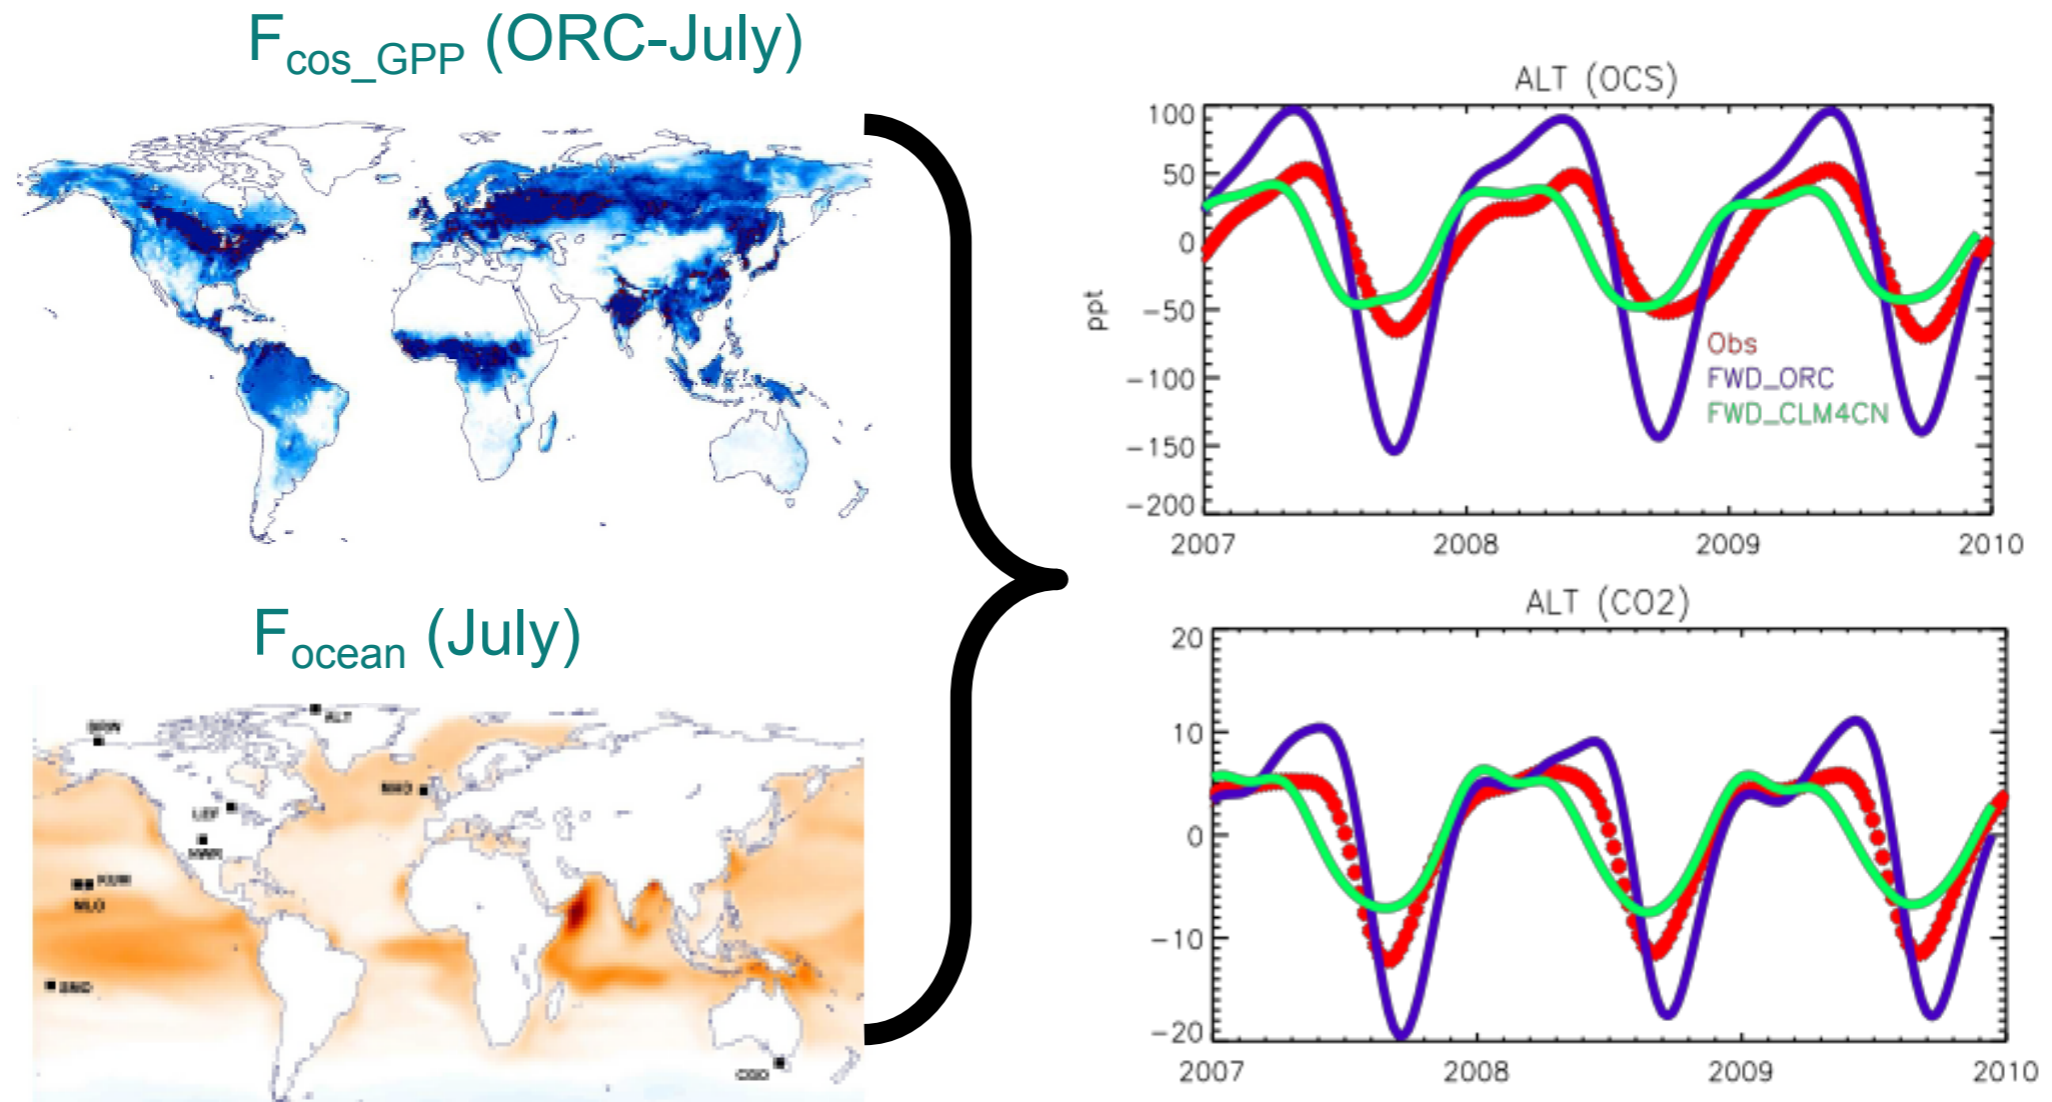

Task 2: Develop novel data fusion techniques for joint surface and space-based carbon cycle data

Progress

- LSCE and WU made their ‘base simulations’ in the summer of 2018, and fed them to task 3 for benchmarking
- LSCE performed first inversions with NASA OCO-2 XCO₂, and is now preparing for joint XCO₂ NASA and Bremen FoCAL-OCO₂), SIF (NASA and KNMI), and OCS inversions (**example follows**)
- WU created a new “long-window” inversion in which 0.5x0.5 degree monthly retrieved SIF-anomalies (KNMI-SIFTER and NASA) drive interannual variations in net ecosystem exchange alongside CO₂ surface observations (**—> Poster Liesbeth**)
- MPI created high-resolution (0.25 degree) satellite inversion system for Europe that can ingest XCO₂ and various other satellite products, to be nested in global TM3 runs (**example follows**)

Simulated [OCS] & [CO₂] with LMDz at LSCE: illustration with 2 land carbon models (ORCHIDEE & CLM4CN) and compared with NOAA measurements at station Alert (Canada)

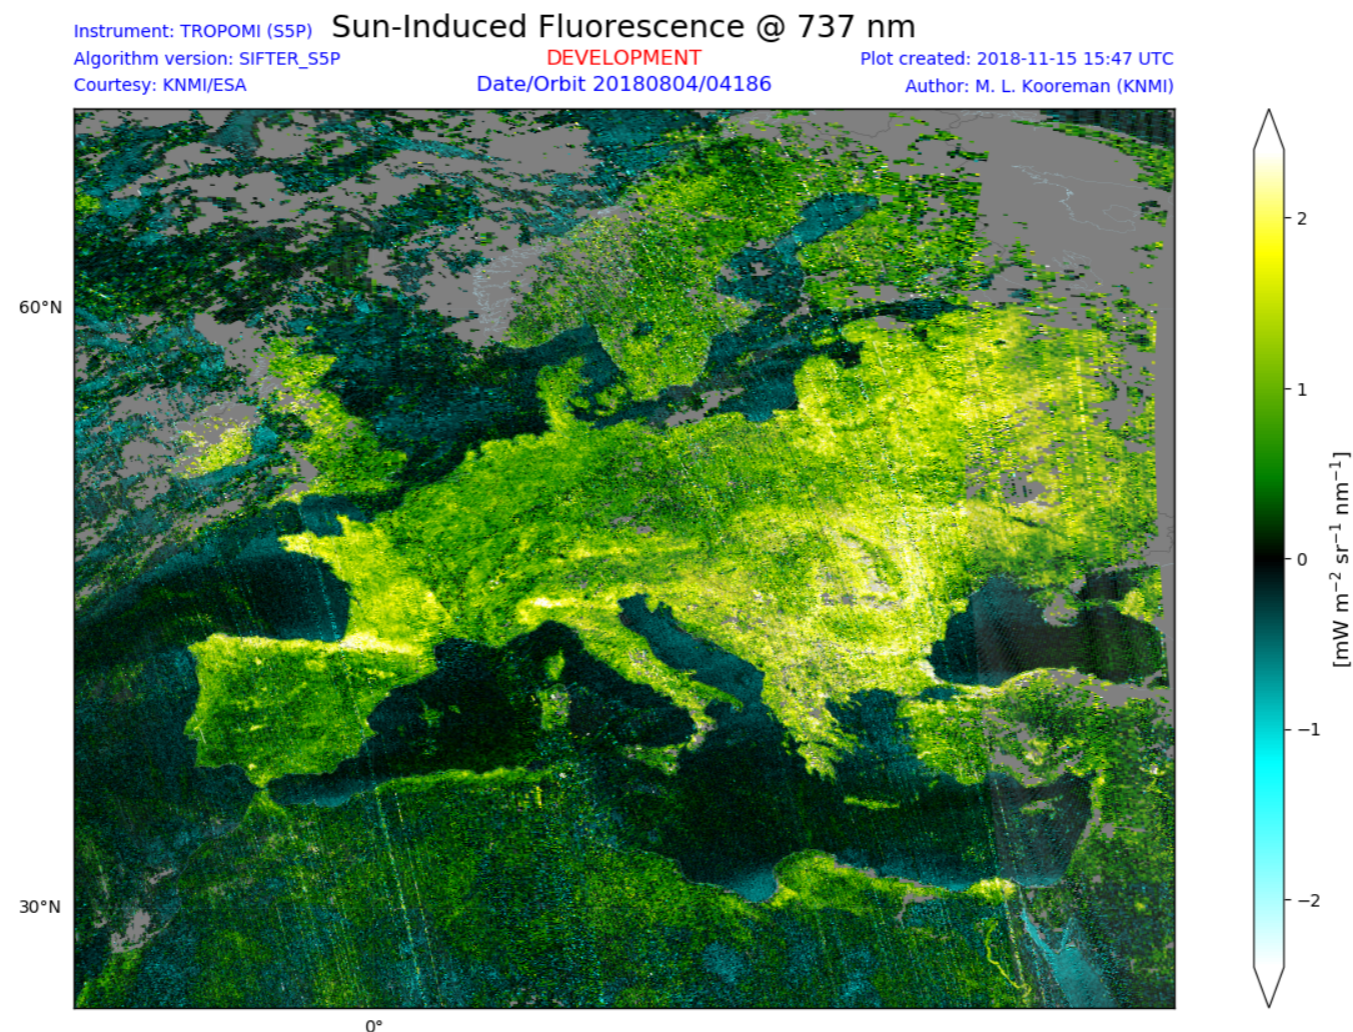

- ORCHIDEE has too large GPP amplitude at high latitudes
- CLM4CN shows an advance of phase for GPP at high latitudes

We expect to constrain the phase and the amplitude of GPP with OCS. Addresses Grand Challenge #3

WU: Parameter optimization in a simple surface flux model

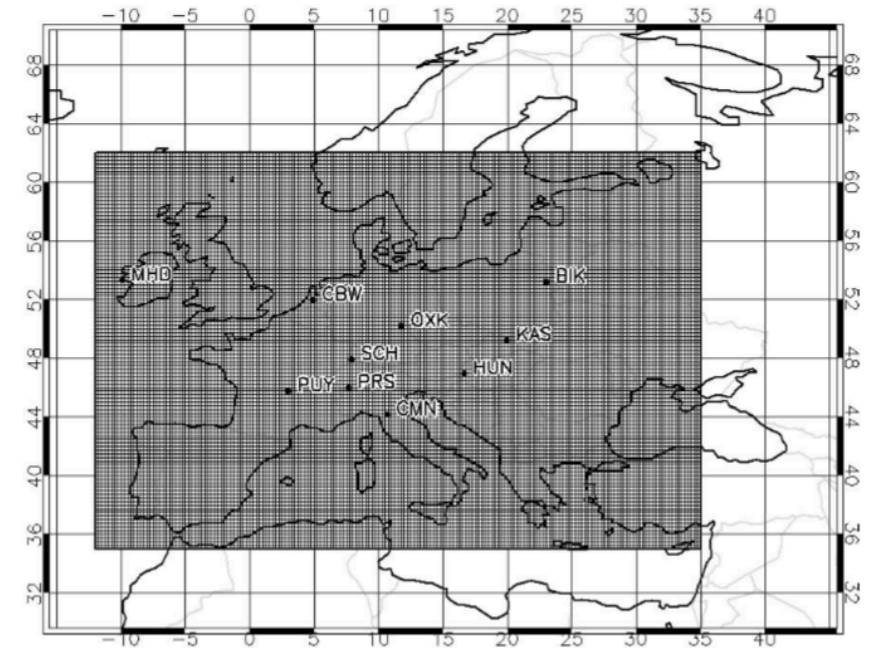

- Rationale:
 - Use satellite data (e.g. SIF, NIR_v) as proxy for anomalies and spatial patterns

See Poster **Liesbeth Florentie**

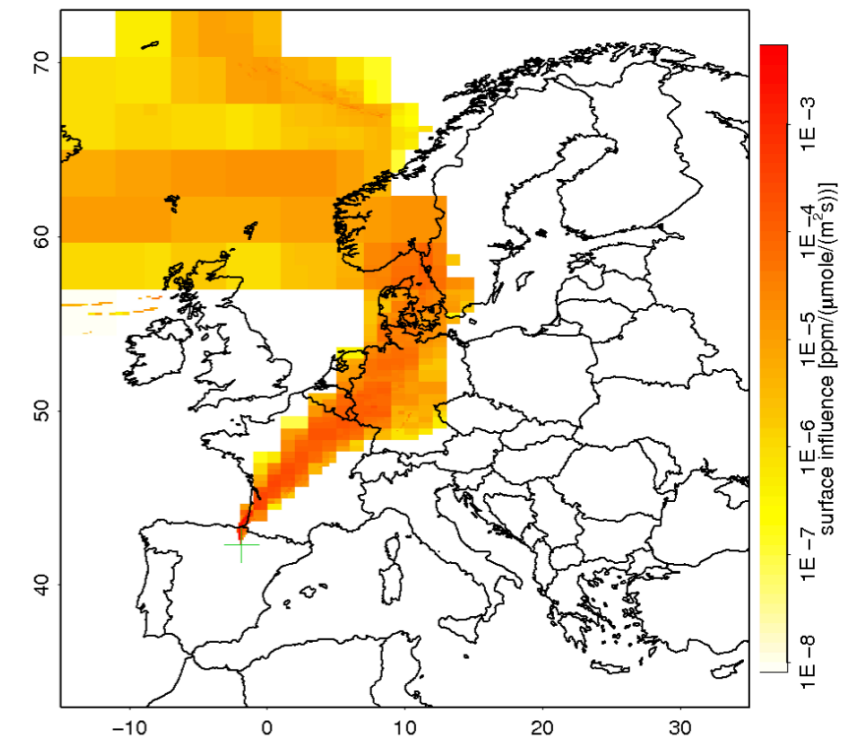

Nested regional inversions (MPI)

- Based on established nested TM3-STILT 2-step inversion
- *Progress*
 - Implementation of Lagrangian column operator in STILT, based in part on X-STILT from Wu et al., 2018
 - Allows for inclusion of satellite measurements in 0.25 degree regionally nested inversions already performed for Europe

Trusilova et al., 2010

Footprint of a single GOSAT sounding from October 2011

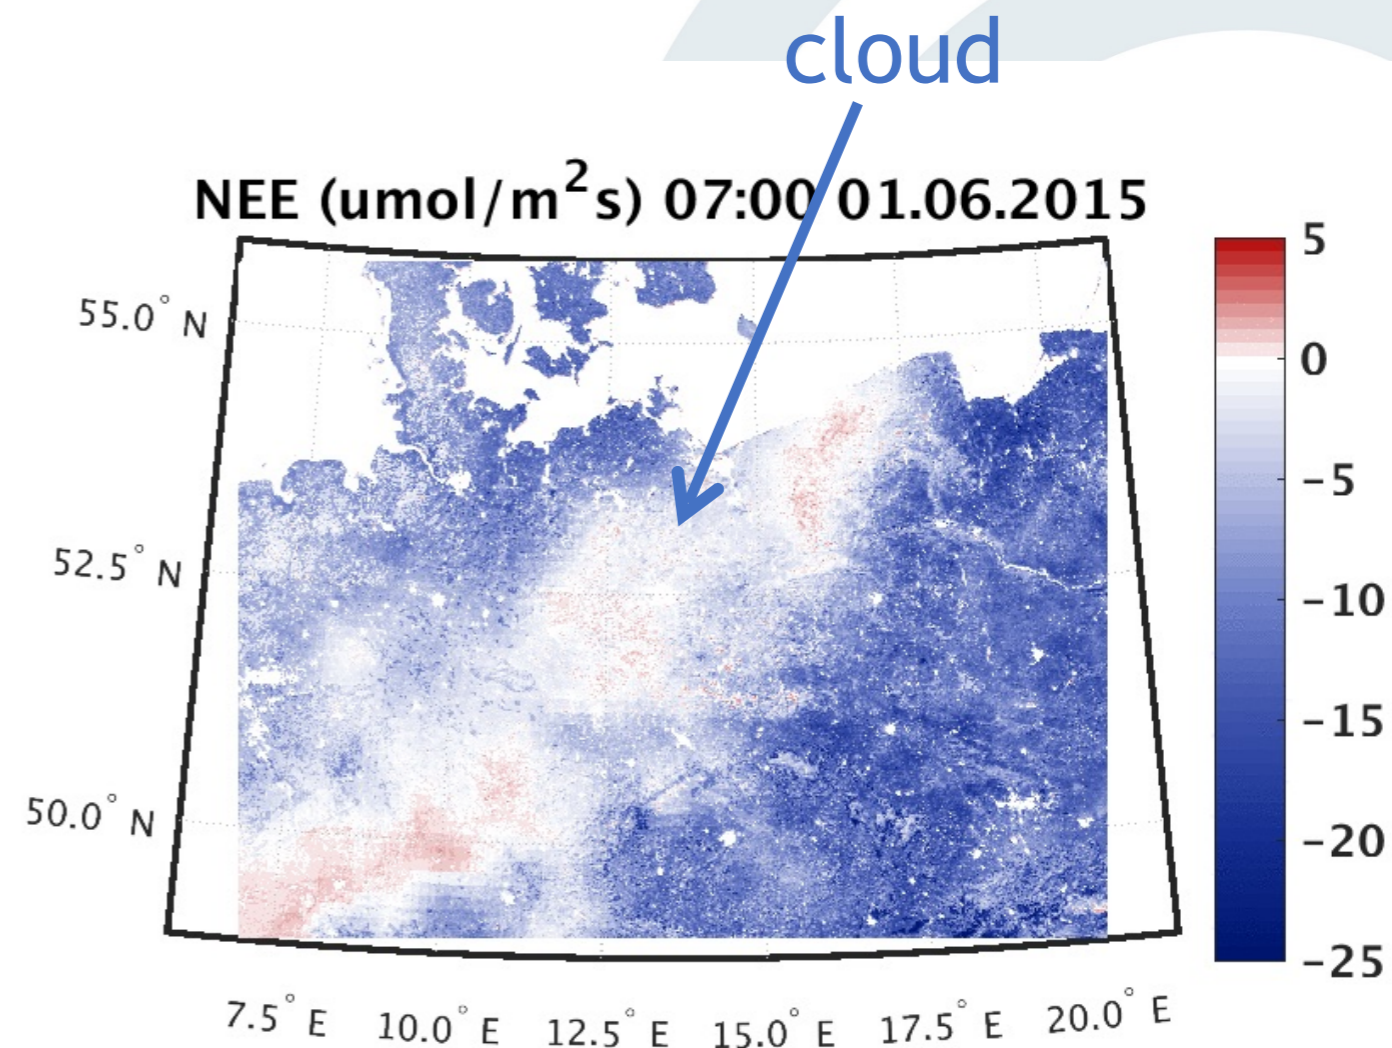

Nested regional inversions (MPI)

- *Plans*

- To be coupled with high-resolution (cloud-resolving) VPRM prior
- To be tested for simulation period in 2015

- *Impact*

- Will test for impact of clear-sky bias in the interpretation of satellite measurements, addressing Grand Challenges #1 and #3

Task 3: Reconcile carbon source/sink estimates from different top-down approaches with each other, and with bottom-up constraints

- *Objectives*

- Reconcile existing and new results on the global and regional carbon balance
- Implement a system that allows fast and easy assessment of data assimilation system results on an open-access platform.

- *Progress*

- Protocol for delivery of model results created and agreed
- Test with four models (2x CHE, 2x external) done for GCP2018 release
- Open-source based analysis on ICOS Carbon Portal implemented and used for comparisons
- Prototype benchmarks based on aircraft CO₂ data, and new one to be developed based on TCCON XCO₂ columns

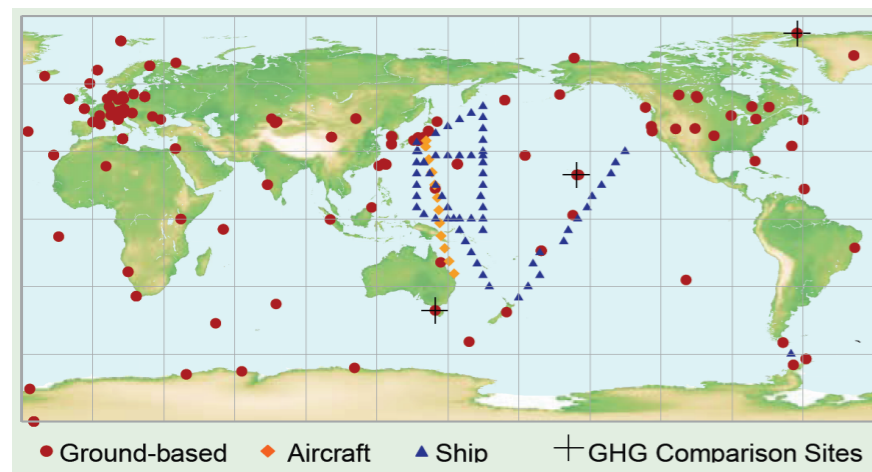

- *Impact*

- Community engagement in benchmarking inverse runs
- Contributed to published Global Carbon Balance in 2018
- Shared platform development with EUROCOM, VERIFY, and CARBAM

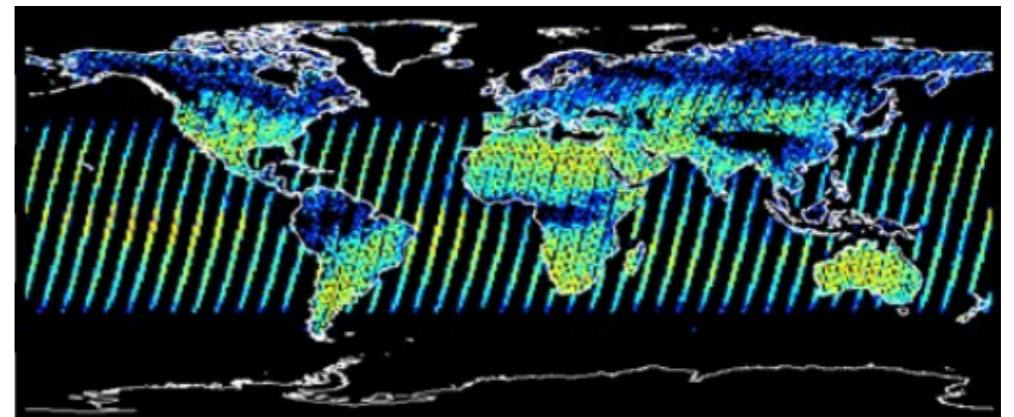

Benchmarking inverse systems: Top-down inversions from satellite and surface data

Atmospheric inversions using the surface CO₂ measurement network:
Sparse coverage. CO₂ measurement accuracy <0.2 ppm

1. Copernicus Atmospheric Monitoring Service (LMDZ)
2. Jena CarboScope s76 (TM3)
3. Carbon Tracker (TM5)

Atmospheric inversions using satellite CO₂ measurements
GOSAT: Global (sort of) coverage ~every 3 days, CO₂ measurement accuracy 2-3 ppm

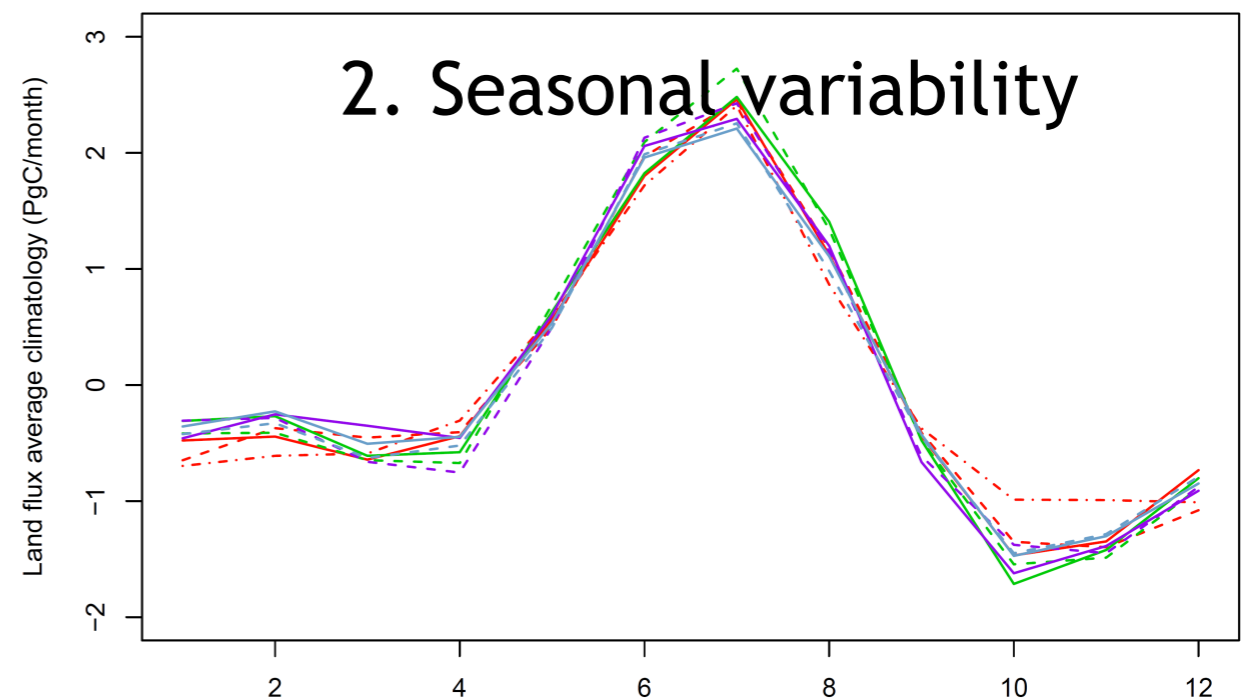

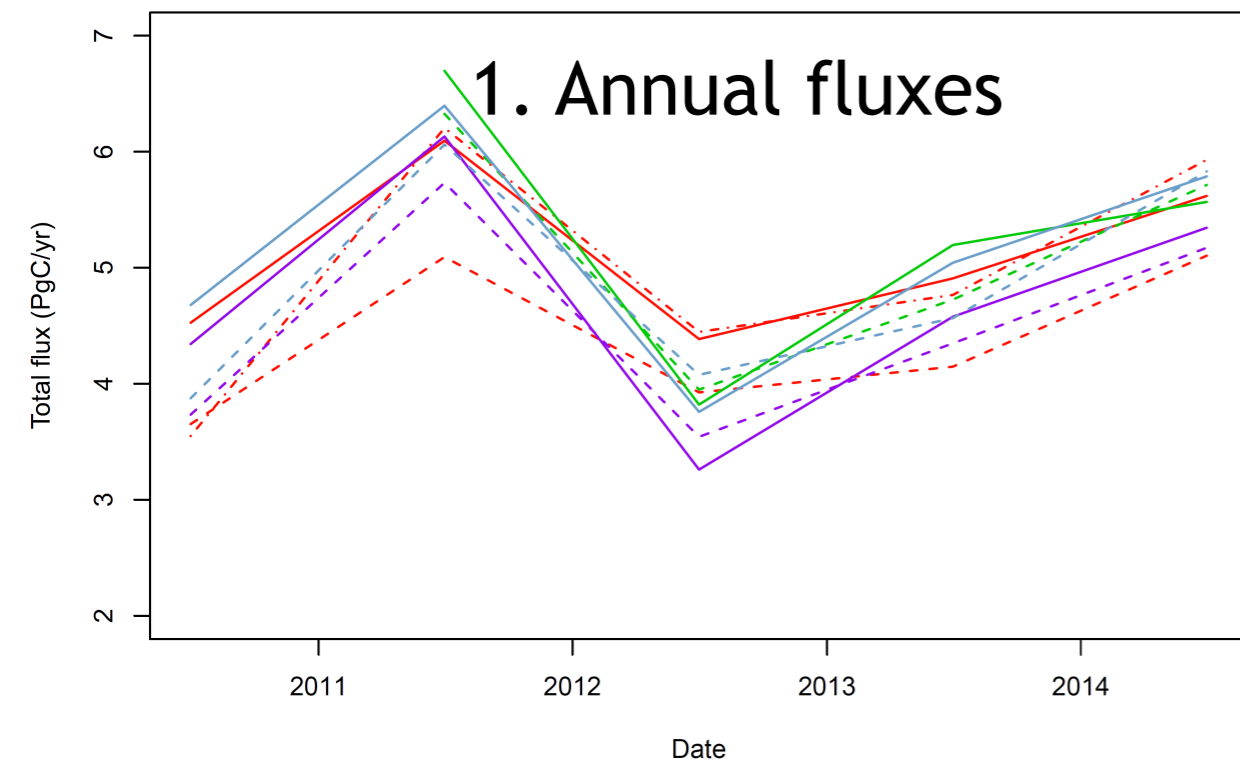

Satellite retrieval algorithm	Provider of satellite data	Transport model	Provider of inversion
OCFP (from GOSAT)	University of Leicester	LMDZ	LSCE
		TM3	MPI-BGC
		TM5	SRON
SRFP (from GOSAT)	SRON/KIT (Netherlands Institute for Space Research/Karlsruhe Institute of Technology)	LMDZ	LSCE
		TM3	MPI-BGC
		TM5	SRON

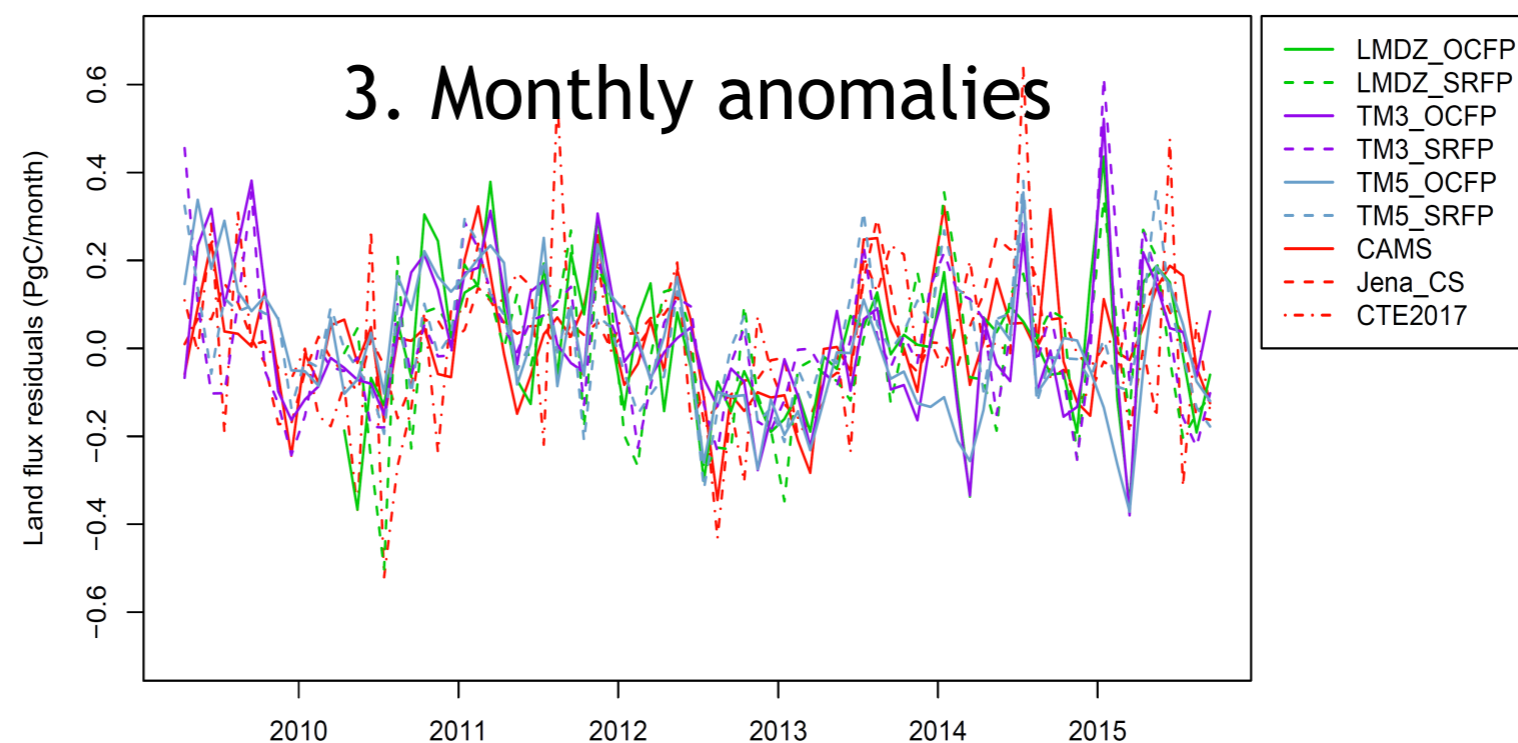

Benchmarking inverse systems: Top-down inversions from satellite and surface data

Global total flux

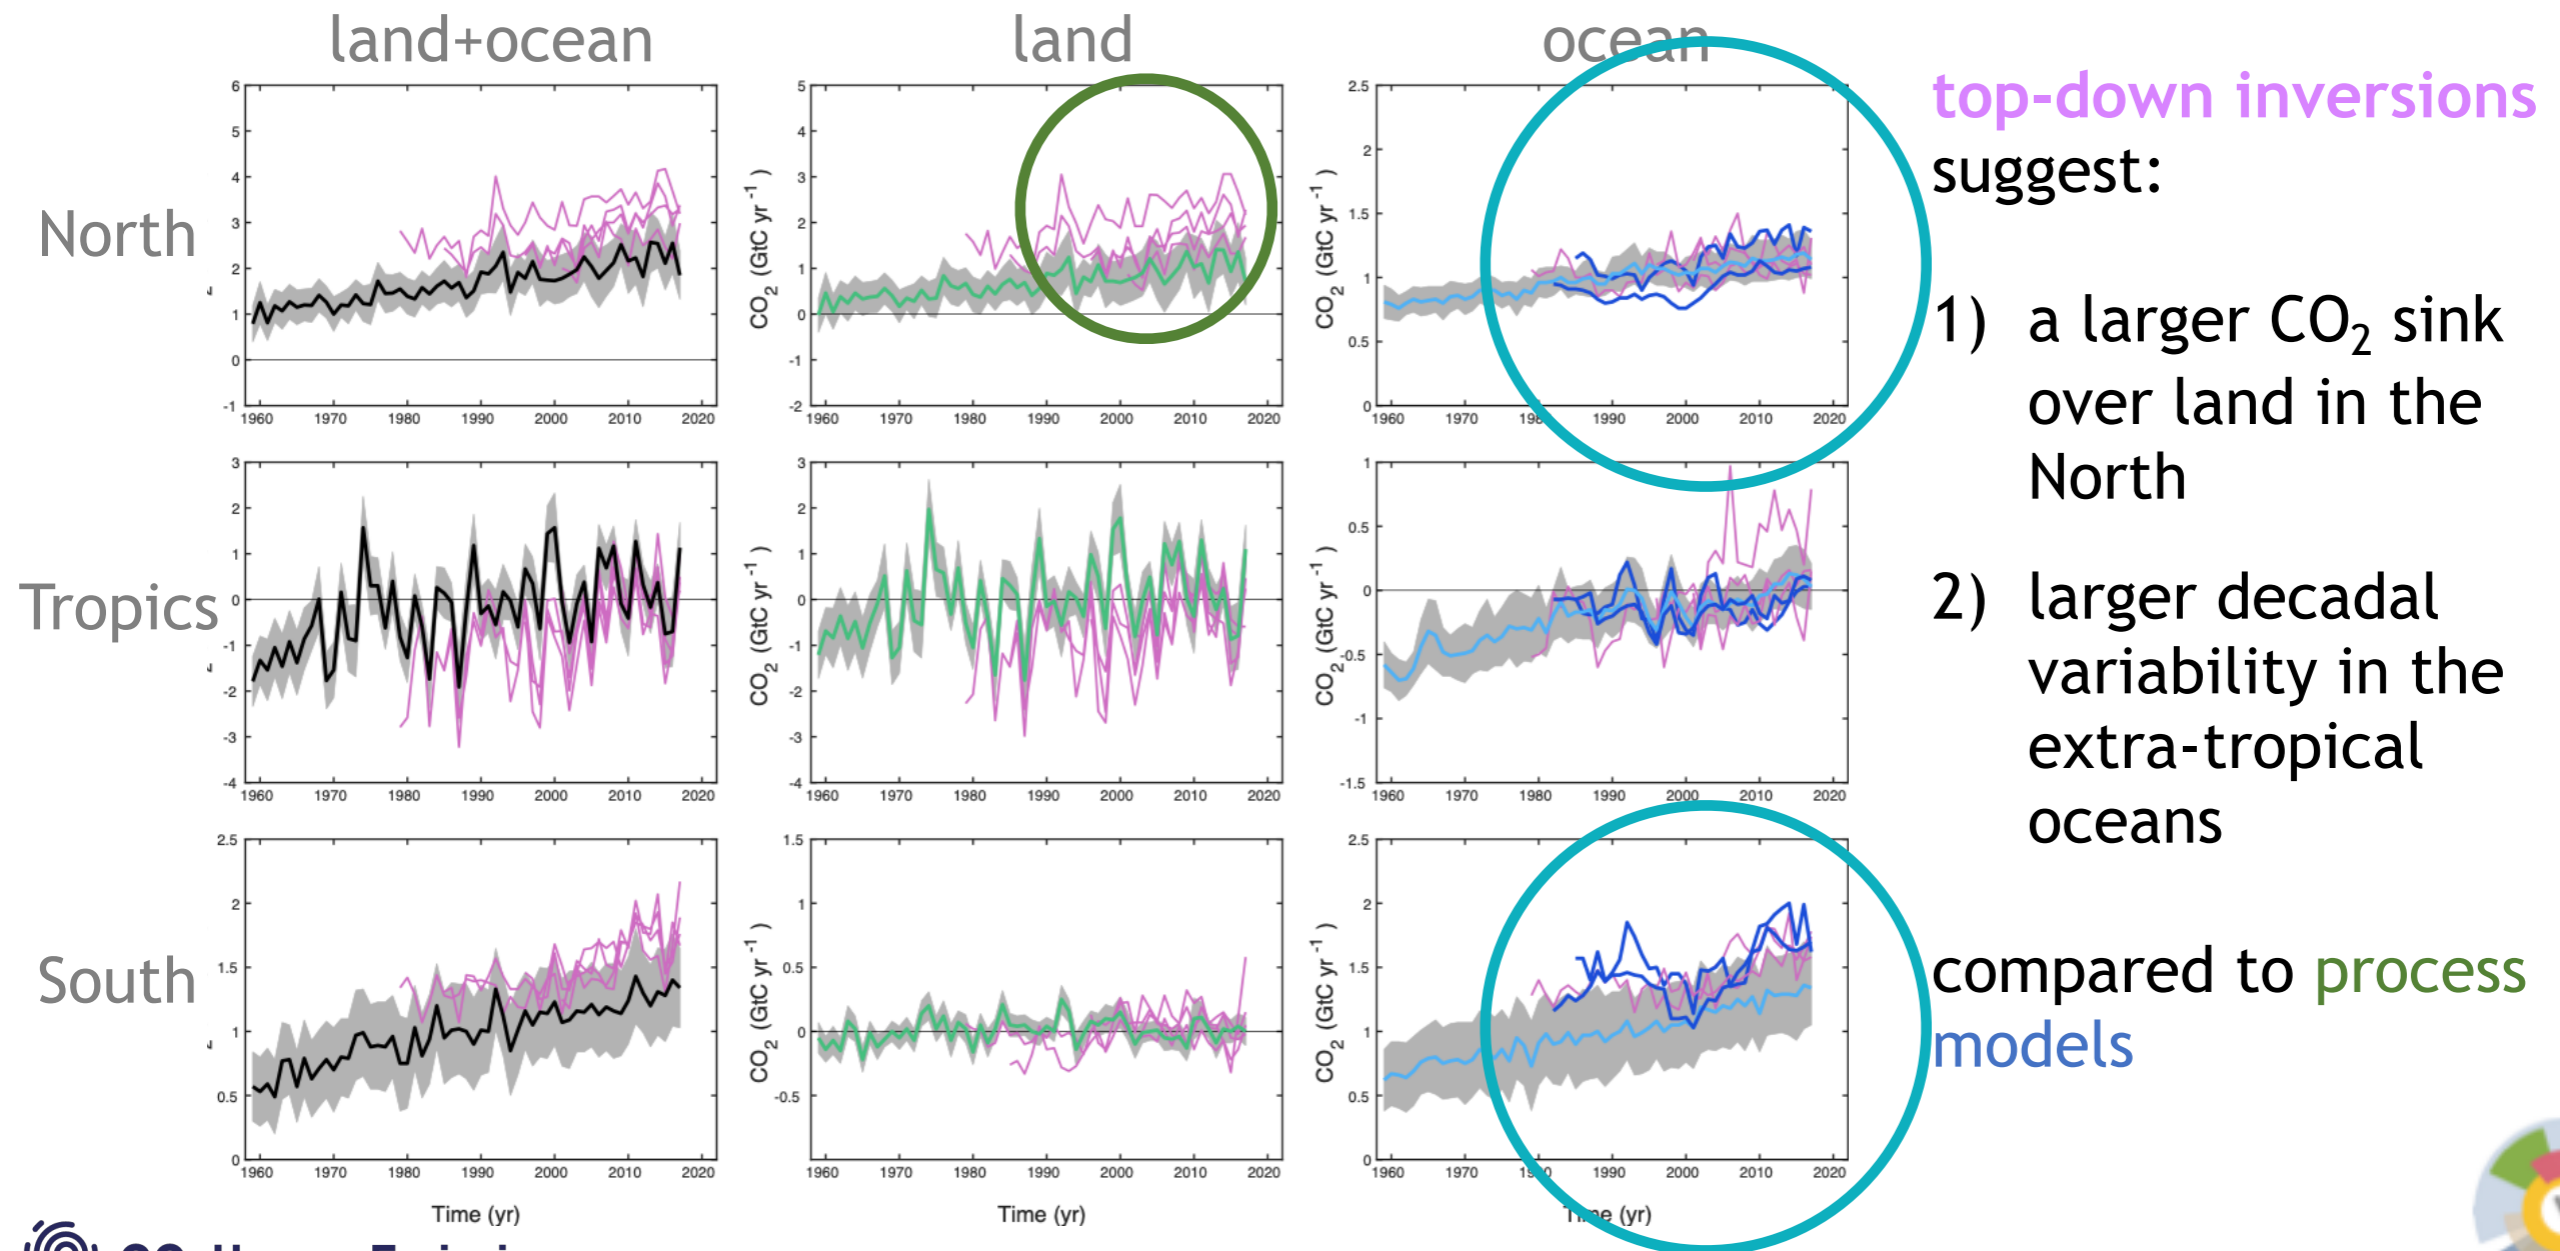

Global land flux average climatology for 2010–2014
(for 2011–2014 for LMDZ)

Global land flux residuals

Comparison of top-down inversion based on surface data and bottom-up process models

Task 3 impact and plans

- Benchmarking in Task 3 is becoming the standard approach for Global Carbon Project, EUROCOM, and CHE
- New metrics are actively developed
- Next target: recent key events like 2018 drought, 2015/2016 El Nino
- Online analysis platform to expand to new users and projects
